## Temporal Trends in Abundance: Alternative Model Fits

In addition to the continuous piece-wise model described in the main body of the paper to compare regression slopes before and after 1992, we fit two other models to evaluate the robustness of our results. The first was a less biologically realistic, discontinuous piece-wise model with no continuity constraint

$$\ln(SSB_t) = \alpha + \delta_\alpha \eta_t + (\beta + \delta_\beta \eta_t) t + \epsilon_t \quad (1)$$

where  $\delta_\alpha$  is the change in intercept post-1992. The equations used for the continuous and discontinuous piece-wise models assume independence and that variability around the mean arises from measurement error. Thus, for comparison, we also fit a random-walk state-space model (Durbin and Koopman 2001) with pre- and post-1992 drift terms via a Kalman filter with measurement and process error estimation attempted:

$$\ln(SSB_{obs,t}) = \ln(SSB_{true,t}) + \nu_t \quad (2)$$

$$\ln(SSB_{true,t+1}) = \ln(SSB_{true,t}) + \beta + \delta_\beta \eta_t + \zeta_t \quad (3)$$

where  $SSB_{obs,t}$  the assessment-derived spawning stock biomass in year  $t$ ,  $SSB_{true,t+1}$  is the estimate of the true state of the spawning stock biomass, and  $\nu_t$  and  $\zeta_t$  are the normally distributed measurement and process errors, respectively. The equations for all three models use the same parameter symbols for continuity but each will have a model-specific interpretation. The random-walk state-space model consistently yielded estimates of low to absent measurement error variability. This had the effect of reducing the model to a process-variance model where the model fit often, but not always, conformed closely with the observed data. The near absence of measurement error variability can be attributed to either the low-frequency nature of the time series, which presumably resulted from the assessments being aggregated across multiple ages and cohorts, thus producing a relatively smooth biomass series where the error variances are difficult to separate, or the relative simplicity of the implemented state space model (Equation 3).
