SCIENTIFIC COUNCIL MEETING – JUNE 2008

A Revised ASPIC Based Assessment of Redfish in NAFO Divisions 3LN

by

A. M. Ávila de Melo [1], R. Duarte [1], D. Power [2], and R. Alpoim [1]

Abstract

There are two species of redfish in Divisions 3L and 3N, the deep-sea redfish (*Sebastes mentella)* and the Acadian redfish (*Sebastes fasciatus*) that have been commercially fished and reported collectively as redfish in fishery statistics. Redfish in Div. 3LN is regarded as a management unit composed of two Grand Bank populations from those two very similar redfish species. The present assessment is based on the results of a non-equilibrium surplus production model (ASPIC Prager, 1994, 2004 and 2007), adjusted to a standardized catch rate series (Power, 1997) and to most of the stratified-random bottom trawl surveys conducted by Canada and Russia in various years and seasons in Div. 3L and Div. 3N, from 1978 onwards. All input series consist of annual observed values and were given equal weight in the analysis. As regards Canadian surveys, only Campelen data and Engel data converted into Campelen equivalents are used in this assessment.

The assessment was preceded by an exploratory analysis with different data formulations derived from the available data series, and a sensitive and retrospective analysis with the chosen input formulation. The assessment was then carried out with ASPIC on bootstrap mode (1000 trials based on the random re-sampling of *cpue* and survey log residuals) giving bias corrected estimates of model parameters, relative biomass (B/B_{msy}) and relative fishing mortality (F/F_{msy}) trajectories, with associated 50% and 80% confidence intervals. Biomass and fishing mortality rates were finally projected (2008-2012/2013) under a low constant catch regime (5000 ton). The stock trajectory related to the surplus production analysis shows a biomass rapidly declining to bellow B_{msy} when fishing mortality rate rises from just above to well above F_{msy} (1986-1987), and a biomass rapidly returning to above B_{msy} after fishing mortality drops to well bellow F_{msy} (1993-1994). A constant catch level of 5000 ton will keep the redfish in Div. 3LN in its present safe zone, with the lower 80% CL of relative biomass well above the B_{msy} level and the upper 80% CL of relative fishing mortality rate well bellow the F_{msy} level. Finally, in order to test if these projection results are robust or if they might be affected by differences on results from previous assessment, the same projection exercise was performed starting one year earlier (2007). Regardless the retrospective bias between the two assessments both runs shown the stock at the same high level relative to B_{msy} , five-six years after the reopening of a directed fishery at a small scale of 5000 ton.

Introduction

There are two species of the genus *Sebastes* that have been commercially fished in Div. 3LN, the deep sea redfish (*Sebastes mentella)*, with a maximum abundance at depths greater than 300m, and Acadian redfish (*Sebastes fasciatus*), preferring shallower waters of less than 400m. Due to their external resemblance *S. mentella* and *S. fasciatus* are commonly designated as beaked redfish.

Beaked redfish are viviparous with the larvae eclosion occurring right before or after birth, long living and slow growing, with females attaining size of 50% maturity at 30-34cm (Power, 2001). Both species have pelagic and demersal concentrations as well as a long recruitment process to the bottom. Their external characteristics are very similar, making them difficult to distinguish, and as a consequence they are reported collectively as “redfish” in the commercial fishery statistics. For the same reason *S. mentella* and *S. fasciatus* are treated as a single species in the Grand Bank surveys carried out by Canada, Russia and more recently by EU-Spain.

This redfish assessment regards the beaked redfish in Div. 3LN as a management unit composed of two Grand Bank fish populations of two very similar species. Nevertheless, it is accepted that in this management unit *S. mentella* is the dominant population, representing almost 100% of the commercial catch and the major proportion of the exploitable redfish biomass in Divisions 3L and 3N.

The 2007 assessment (Ávila de Melo *et al.*, 2007) was based on a non-equilibrium surplus production model (ASPIC Prager, 1994, 2004 and 2007), adjusted to a standardized catch rate series (Power, 1997) and two series of stratified bottom trawl surveys on Div. 3L and Div. 3N, covering from 1991 onwards almost the entire area of redfish distribution in north and south east Grand Bank. The assessment was preceded by an exploratory analysis of different data formulations derived from the available data series, using a traffic light framework to evaluate the diagnostics of the ASPIC runs. In order to reduce non explained variability and improve the fit of the ASPIC model to the available biomass indices two different categories of the data set formulations were considered: one based on the original annual values of each biomass index and the other where the annual values were smoothed by 3-year moving averages. The results of the exploratory analysis lead to the conclusion that the use of moving average formulations allowed a better ASPIC FIT than the one with the observed annual data series. So the moving average formulation incorporating both CPUE and spring and autumn survey series in their full extension was the one chosen to pursue with last year assessment.

STACFIS recognized ASPIC as a useful tool to carry out an analytic assessment of the 3LN redfish stock (NAFO 2007), but didn’t accept the 2007 assessment based on two major concerns regarding the chosen input formulation:

“*Regardless of the wide inter-annual variability of the observed CPUE and survey data and poorer fit of the model, the original values of each biomass index provide very similar results namely as regards relative biomass and fishing mortality trajectories and should be used instead of moving averages;*

From the early 1980s to the beginning of the 1990s, when catches were quickly raised from a previous average level of 21 000 tons (1965-1985) to a much higher average level of 41 500 tons (1986-1992), including a peak of 79 000 tons in 1987, available survey data from Canadian summer survey on Div. 3L (1978-1979, 1981, 1984-1985, 1990-1991 and 1993) and Russian trawl survey on Div. 3LN (1983-1993) suggests that stock size suffered a substantial reduction. However throughout this period stock dynamics from ASPIC basically rely on the CPUE series. In order to capture the full extent of this former stock decline ASPIC input should include the observed biomass indices from the two above mentioned survey series.

Therefore, STACFIS recommends that a revised ASPIC model utilizing (1) the original values of cpue and survey indices and (2) incorporating additional Canadian 3L summer and Russian 3LN survey series be evaluated during the interim assessment of redfish in Div. 3LN at the June 2008 Scientific Council meeting”.

The present assessment goes beyond the 2007 STACFIS guidelines, incorporating most of the survey biomass indices available for this redfish stock, not only from the Canadian summer survey on Div. 3L and Russian bottom trawl survey on Div. 3LN, but also from the Canadian winter and autumn surveys on Div. 3L, with all input series presented as annual observed data.

Nominal catches and TAC's

Reported catches from Div. 3LN declined from 45 000 to 10 000 ton on the first years of catch records (1959-1964) and oscillated over 21 years afterwards (1965-1985) around 21 000 tons average level. Catches increased sharply to a 79,000 tons high in 1987 and fall steadily afterwards to 450 tons in 1996. From 1986 till 1993 reported catches exceeded TAC's, but in the rest of the years prior to the close of the fishery catches fell well bellow annual TAC's. The NAFO Fisheries Commission implemented a moratorium on directed fishing for this stock since in 1998.

Catch increased to 900 tons in 1998, the first year under a moratorium on directed fishing, with a further increase to 3 100 tons in 2000. Catches declined in 2001-2003 and were stable in 2004-2005 at 650 tons level. Catch almost reached the historic low level in 2006 with 496 tons, but recorded over a tree times fold increase in the final year, with a STACFIS catch estimate of 1664 tons (Table 1, Fig. 1).

Description of the fishery

In the early 1980's the former USSR, Cuba and Canada were the primary fleets directing for redfish in Div. 3LN. The rapid expansion of the fishery was due to the entry of EU-Portugal in 1986 and South Korea in 1987, along with various re-flagged fleets. In the early 1990's Russia and the Baltic mid-water trawlers, together with South Korea and Portuguese bottom trawlers, were still responsible for the bulk of fishing effort, concentrated by that time on the "Beothuk Knoll" (Div. 3LMN border, southwest of the Flemish Cap).

South Korea left the area by the end of 1993 and from 1994 onwards the other fleets reduced effort substantially on Div. 3LN. The quick decline of redfish catch rates was the main reason for this reduction of redfish fishing effort, and justified its partial shift southeast to Div. 3O. Since 1994 most of the redfish catches in NAFO Divisions 3L and 3N were taken as by-catch of the Greenland halibut fishery pursued from the northern slopes of the Sackville Spur in Div. 3L through Flemish Pass till the canyons of northern Grand Bank in Div. 3N. The EU-Spain and EU-Portugal bottom- trawl fleets became the main fleets responsible for the 3LN redfish by-catch over moratorium years, with EU Portugal recently taking most of the by-catch (2006 and 2007).

Commercial Fishery Data

Catch and Effort

On the 1997 assessment (Power, 1997) catch/effort data for Div. 3L and Div. 3N from 1959 to 1995 were analyzed with a multiplicative model (Gavaris, 1980) in order to derive a catch rate series for each division standardized for country-gear-tonnage class, NAFO division, month, and amount of by-catch associated with each observation. Both CPUE series shows much within year variability over time, with no statistically difference between the catch rates for most of the years. The assessment considered that catch rate indices for Div. 3L and Div. 3N were not reflective of year to year changes in population abundance but they may be indicative of trends/patterns over longer periods of time.

This assessment recovers the predicted effort series in fishing hours for Div. 3L and Div. 3N from the 1997 multivariate analysis, in order to derive a single annual catch rate for Div. 3LN: for each year of the 1959-1994 interval this standardized catch rate is given by the ratio between the sum of Div. 3L and Div. 3N STATLANT catch (thousand tons) and the sum of Div. 3L and Div. 3N predicted effort (fishing hours) (Table 2). Annual catch rate for Div. 3LN was finally scaled (difference between each observation and the mean, scaled to the standard deviation of the series) in order to be presented on Fig. 2. Catch rates for Div. 3LN were above average from 1959 till 1965, increasing on the first years of the time series, oscillate around the average on the intermediate years and start declining from 1987 onwards. On the final years, 1990-1994, catch rates were stable at a minimum level well bellow average.

Commercial fishery sampling

Most of the commercial length sampling data available for the 3LN beaked redfish stocks came, since 1990, from the Portuguese fisheries and has been annually included in the Portuguese research reports on the NAFO SCS Document series (Vargas *et al*., 2008). Taking into account that the majority of the length sampling was from depths greater than 400m, these data should represent *S. mentella* catches. Length sampling data from Spain and Russia were used to estimate the length composition of the commercial catches for those fleets in 2003-2005 and 2003-2007 respectively (González *et al*., 2006; Vaskov *et al*., 2008). The 1990-2007 per mille length composition of the Portuguese trawl catch was applied to the rest of the commercial catches (Table 3a). In all cases the 3LN beaked redfish length weight relationships, used to compute each absolute length frequency vector of the 3LN redfish commercial catch (Table 3b), were derived from individual length /weight observations collected annually through the sampling on board of the Portuguese by-catches from both Divisions 3L and 3N (Alpoim and Vargas, 2004; Vargas *et al*., 2008). The 1998 length weight relationship was applied to the previous years, back to 1990.

The annual mean length of the catch was calculated as a weighted mean of catch numbers at length for each year (Table 3a). The overall mean length of the 1990-2007 catch (arithmetic mean of the annual mean lengths of the commercial catch) was used to derive the anomalies in the mean length on the 3LN beaked redfish commercial catch over this period (Table 3a, Fig. 3). The proportion of small redfish (less than 20cm) in the catch is presented as well, in Table 3a. The purpose of the first exercise (length anomalies) was to detect eventual shifts in the length structure of the commercial catch or by-catch that could reflect changes in the exploitable stock structure. As for the second exercise (proportion of small redfish), a sudden and important increase on the proportion of small redfish in the catch could be regarded as signal of the income of a good recruitment.

Stability in the length structure of the catch/by-catch is observed through the 1990-2007 interval, with no clear pattern on length anomalies detected over time (Fig. 3). Higher negative anomalies are coupled with higher proportions of small redfish in 1991, 1998, 2003 and 2006 suggesting the income in those years of above average recruitments to the exploitable stock, from year classes 4-5 years back in time.

Research Surveys

From 1978 till 1990 several stratified-random bottom trawl surveys have been conducted by Canada in various years and seasons in Div. 3L. However only since 1991 Canadian stratified-random surveys covered both Div. 3L and Div. 3N on a regular annual basis: a spring survey (May-Jun.) and an autumn survey (Sep.-Oct. 3N/Nov.-Dec. 3L for most years). The design of the Canadian surveys was based on a stratification scheme down to 732 m for Div. 3LN (Doubleday, 1981). From 1996 onwards the stratification scheme has been updated to include depths down to 1 464 m (800 fathoms) (Bishop, 1994), but only the autumn surveys have swept strata bellow 732 m depth, most on Div. 3L.

Up until the autumn of 1995 the Canadians surveys were conducted with an Engels 145 high lift otter trawl with a small mesh liner (29 mm) in the codend and tows planned for 30 minute duration. Starting with the autumn 1995 survey in Div. 3LN, a Campelen 1800 survey gear was adopted with a 12 mm liner in the codend and 15 minute tows utilizing SCANMAR. A comparison of the generated data with the original Engel data suggested overall trends in abundance were the same except that the relative measure of abundance estimated for the Campelen trawl conversions were higher (Power and Parsons, 1998).

According to the headers on the original spreadsheets with Canadian survey abundance and biomass data, all surveys on Div. 3L have Engel data converted into Campelen equivalents from 1985 onwards with the exception of the spring survey (conversion since 1980). However for the summer survey the first year of conversion of Engel data remains unclear, since the same figures for the years prior to 1985 on the original spreadsheet with the Canadian summer survey data had been published as Campelen trawl equivalent units as well (Power and Parsons, 1999). So, two alternate series of biomass indices are considered in the assessment for the Canadian summer survey in Div. 3L, one starting in 1978 and the other in 1985.

Abundance and biomass indices have been converted into Campelen equivalents since the start of Canadian surveys on Div. 3N, in 1991. Campelen equivalent data series extended till 1994 (autumn surveys in Div. 3L and Div. 3N) or 1995 (spring surveys in Div. 3L and Div. 3N) and are coupled with the following original Campelen series starting since then. No spring survey was carried out in 2006 on Div. 3N. As regards Canadian surveys, only Campelen data and Engel data converted into Campelen equivalents are used in this assessment.

Since 1983 Russian bottom trawl surveys in NAFO Div. 3LMNO turn to stratified-random, following the above mentioned Canadian stratification for Sub area 3. On 1984 standard tows were set to half hour at 3.5 knots, with a standard gear. From 1984 till 1990, vessels conducting this survey were of the same tonnage class (the BRMT series) with the exception of 1985, when a vessel of smaller tonnage class (PST series) was employed. This smaller category was later employed on the 1991 and 1993 surveys. On 1992 and 1994 no survey was carried out in Div. 3N. On 1995 the Russian bottom trawl series in NAFO Sub area 3 was discontinued (Bulatova *et al.*, 1997).

On 1992 redfish results of the 1984-1991 stratified-random surveys in Div. 3LN by Russia were revised according to standard methodology (Power and Vaskov, 1992).Mean number and mean weight per standard tow were estimated from successful sets only, each tow being adjusted to 1.8 n mi. distance before analysis. Overall mean estimates by year and division were derived from the respective means by strata (weighted by the stratum area) and presented with associated 95% CI's. Survey abundance and survey biomass are finally tabulated by year and division. However in 1994, a Russian research document presents new figures for redfish bottom survey abundance and biomass from the same Russian survey series in Div. 3LN (1984-1991, plus the results of the 1993 survey) (Vaskov, 1994). No details are given regarding the method and the strata used to derive these new figures. The two series (Power, 1984-1991; Vaskov, 1984-1991 and 1993) are considered as alternate biomass indices for Div. 3LN combined from Russian stratified-random surveys.

All the available survey biomass results from the Canadian and Russian stratified-random bottom trawl surveys are presented in Table 4. About 96% of the available biomass data are included in the exploratory analysis preceding the assessment and 88% incorporated in the final framework of the ASPIC assessment.

In 1995 EU-Spain started a new stratified-random bottom trawl spring (May-June) survey on NAFO Regulatory Area of Div. 3NO. Despite changes on the depth contour of the survey, all strata in the NRA till 732m were covered every year, following the standard stratification. From 1998 onwards the Spanish survey was extended to 1464 m (with the exception of 2001, with 1116m depth limit) and in 2004 expanded to the Regulatory Area of Div. 3L. From 1995 till 2000 the survey was carried out by the Spanish stern trawler *C/V Playa de Menduiña* using a *Pedreira* bottom trawl net. In 2001 the *R/V Vizconde de Eza*, trawling with a *Campelen* net, replaced the commercial stern trawler. In order to maintain the data series obtained since 1995, comparative fishing trials were conducted in spring 2001 to develop conversion factors between the two fishing vessel and gear combinations. Former American plaice and Greenland halibut survey indices from C/V *Playa de Menduíña* were transformed to R/V *Vizconde de Eza* units (*González et al.*, 2004), but so far this exercise has not been carried out for beaked redfish. That is the main reason why the Spanish survey data are not yet included in the assessment suite.

Survey biomass and female spawning biomass

All available survey biomass results from the Canadian and Russian stratified-random bottom trawl surveys are presented in Table 4. About 96% of these biomass data are included in the exploratory analysis preceding the assessment and 88% incorporated in the final framework of the ASPIC assessment.

The 1991-2007 spring and autumn survey indices for Div. 3LN combined (biomass and female SSB) are also presented on Table 4. Biomass indices for redfish, derived either from commercial or survey catch rates, typically show large inter-annual variability, too drastic to be only explained by changes in stock abundance from one year to the next. These fluctuations are caused not only by the schooling behaviour of redfish, but also by a wide and "non-uniform" distribution within their geographical and depth limits (all redfish species present both demersal and pelagic concentrations). That is why it is generally accepted that a redfish biomass index represents better a stock trajectory on the long term than the stock size on a short term basis. In order to smooth the wide inter annual variability of the indices, turn the survey series comparable and facilitate the detection of trends within stock dynamics, the survey biomass series used in the assessment and the female SSB survey series were standardized (difference between each observation and the mean scaled to the standard deviations of the series) and so presented on Figure 4a and 4b. From the mid 1980s to the beginning of the 1990s, when catches quickly raised from a previous average level of 21 000 tons (1965-1985) to a much higher level of 41 500 tons (1986-1992), Canadian survey data in Div. 3L and Russian bottom trawl surveys in Div. 3LN suggests that stock size suffered a substantial reduction. Redfish survey bottom biomass in Div. 3LN remained bellow the average level until 1998 and increase to above average level afterwards. A punctual decline is observed in 2002-2004, followed by a consistent increase of the remaining biomass indices over the most recent years.

In order to estimate spring and autumn female spawning survey biomass by division, Div. 3L and Div. 3N female proportion and maturity at length vectors (Power 2001; Ávila de Melo et al., 2005) were applied to the respective 1991-2007 spring and autumn survey abundances at length. Female spawners and stock abundance at length by division were used to calculate female spawning and stock biomass for Div. 3L and Div. 3N as sum of products (SOP), using the 3M *Sebastes sp.* annual length weight relationships (Ávila de Melo et al., 2007). The SOP ratios (SSB/stock biomass) by division were then applied to the respective swept area survey biomasses to give estimates of the 1991-2007 spring and autumn female SSB in Div. 3L and Div. 3N. Finally the sum of these two indices for each survey series gave the spring and autumn female spawning biomass for Div. 3LN combined.

The 1991-2007 standardized female SSB series showed patterns similar to correspondent total survey biomass series over the years, with all observations bellow average before 1998 and most above average afterwards (Fig.4b).

Abundance at length

Spring and autumn survey abundance at length, for Div. 3LN combined, are presented in Table 5a and 5b. Survey abundance at length for each division, year and survey is derived from the correspondent mean number per tow at length, expanded to the survey abundance estimated by the swept area method. The overall 1991-2007 mean length for each survey series (arithmetic mean of the annual mean lengths of the survey abundances at length) was used to derive the spring and autumn survey length anomalies for the stock over this period (Table 5a and 5b, Fig. 5a and 5b). On both survey series all/most of the anomalies during the first half of the 1990's were negative while all were positive between 1996 and 2000. This shift on the survey catch length structure to larger individuals could reflect a relatively high survival of the year classes through the second half of the 1990's. From 2001 onwards length anomalies are either positive or negative with no clear pattern on the spring survey, whereas on the autumn survey most became closer to the overall mean. The lack of a clear pattern on length residuals from both surveys suggests stability on population structure over recent years. With the exception of 1991 and 1992 on the autumn survey, when a couple of large negative residuals are observed probably as a consequence of a pulse on recruitment from the late 1980's, no further signs of other pulses on recruitment are detected.

ASPIC assessment suite

A non-equilibrium surplus production model (ASPIC; Prager, 1994, 2004 and 2007) was used to assess the status of the stock. The model was adjusted to the STACFIS catches (1959-2007, with catches conditioned on *cpue* series) and to the following

Input series:

I1 (Statlant CPUE)	Standardized cpue for Div. 3LN, 1959-1994
I2 (3LN spring survey)	Canadian spring survey biomass for Div. 3LN, 1991-2005, 2007
I3 (3LN autumn survey)	Canadian autumn survey biomass for Div. 3LN, 1991, 1993-1994, 1996-2007
$I4_{Power}$ (3LN Power russian survey)	Russian srping survey biomass for Div. 3LN , 1984-1991 (Power and Vaskov,1992) *versus*
$I4_{Vaskov}$ (3LN Vaskov russian survey)	Russian srping survey biomass for Div. 3LN , 1984-1991 and 1993 (Vaskov,1994)
I5 (3L winter survey)	Canadian winter survey biomass for Div. 3L, 1985-1986 and 1990
I6 (3L summer survey)	Canadian summer survey biomass for Div. 3L, 1985, 1990-1991and 1993 *versus*
I6 (3L full summer survey)	Canadian summer survey biomass for Div. 3L, 1978-1979, 1981,1984-1985, 1990-1991and 1993
I7 (3L autumn survey)	Canadian autumn survey biomass for Div. 3L, 1985-1986, 1990-1994, 1996-2006

All input series consist of annual observed values and were given equal weight in the analysis. On the rest of the analysis each Canadian series is referred by its season and division(s), while the Russian series is referred by its country name. The model assumes that all catchability coefficients are constant over time. Because of the imprecision associated with the estimate of catchability for the various indices, absolute estimates of stock size and fishing mortality are normalized to the stock size and fishing mortality at MSY (B_{msy} and F_{msy} respectively). That is why normalized estimates are included in ASPIC output and used in the printer plots trajectories of biomass and fishing mortality. In a production model fishing mortality refers to catch/biomass ratio.

Basic assumptions

In this assessment the ASPIC version 5.16 fit the logistic form of the production model (Schaefer, 1954). Being K the carrying capacity stock biomass, r the intrinsic rate of stock biomass increase, C the catch biomass, MSY and $Bmsy$ the long term yield and biomass associated with $Fmsy$, the model basic assumptions are:

1) A logistic population growth over time of the unexploited stock (Schaefer, 1954)

$$dB_t / dt = rB_t - (r/K)B_t^2 \qquad (1)$$

2) For an exploited stock catch is also incorporated in the population growth

$$dB_t / dt = rB_t - (r/K)B_t^2 - C_t \qquad (2)$$

3) The biological reference points are

a. $$MSY = rK/4 \qquad (3)$$

b. $$Bmsy = K/2 \qquad (4)$$

c. $$Fmsy = r/2 \qquad (5)$$

Starting with user guesses for the key parameters, Initial Biomass (as a ratio to *Bmsy*), *K*, *MSY* and catchability coefficients for each biomass index, ASPIC generate iteratively estimates of expected biomass indices for each series of observed indices. The key parameters of the model are found by a minimization routine for log squared residuals of *cpue* and biomass from each input survey series.

A summary of the ASPIC model (Prager, 1994) can be found on the 2003 assessment of redfish in Div. 3M (Ávila de Melo *et al.*, 2003).

Input file settings

The ASPIC Ver. 5.16 (Prager, 2005) requires from the user a set of initial definitions/starting guess /constraints that have been specified in the input file as follows:

Line 1: Both `FIT` and `BOT` program modes were used. Starting guesses and minimum and maximum bounds were kept constant from FIT to BOT mode.
Line 2: Fit the `LOGISTIC` (Schaefer) model with condition fitting on `YLD` (yield) and SSE (sum of squared errors) as objective function.
Line 4: `1000` Number of bootstrap trials when running on BOT mode.
Line 11: `0d0` No penalty term in objective function for B1>K (biomass on the 1st year of the assessment greater than carrying capacity biomass).
Line 12: 7 data series are to be analyzed as biomass index of the stock (Statlant CPUE, five Canadian and one Russian surveys).
Line 13: `1d0 1d0 1d0 1d0 1d0 1d0 1d0` When computing the objective function the squared residuals of each one of the 7 data series have equal weight.

Line 14: `0.5d0` Starting guess for $B1/K$ = 0.5, the biomass on the 1st year of the assessment is at B_{msy} level.
Line 15: `2.0d4` Starting guess for *MSY* = 20000 ton. Between 1965 and 1985 catches oscillated with no trend around 21000, catch rates declined when catches were raised above that level.
Line 16: `2.000E+05` Starting guess for carrying capacity *K* = 200000 ton, twice the highest observed level of survey biomass (autumn survey average 1998, 2000-2001).
Line 17: `9.007E-06 0.658d0 1.0d0 0.658d0 0.322d0 0.275d0 0 .275d0` Starting guess of catchability for: STATLANT cpue (derived from *q* of Statlant CPUE for Div. 3M redfish ASPIC assessment, Ávila de Melo *et al.* 2003); spring survey in Div. 3LN combined (average size of spring survey biomass relative to autumn survey biomass, 1991-2005); autumn survey in Div. 3LN combined (a conservative guess, assuming that autumn survey biomass is a proxy of absolute stock biomass); Russian survey in Div. 3LN combined (all Russian surveys in Div. 3LMNO were made between March and July, so the same starting guess for catchability as the Canadian spring survey); winter survey in Div. 3L (average spring survey in Div. 3L/Div. 3LN ratio times average spring in Div. 3LN/autumn Div. 3LN ratio); summer and autumn survey in Div. 3L (average autumn survey Div. 3L/Div. 3LN ratio).
Line 18: `1 1 1 1 1 11 1 1 1` All key parameters of the model ($B1/K$, *MSY*, *K*, $q_{cpue,}$ $q_{spring3LN}$, $q_{autumn3LN,,}$ $q_{Russiann3LN,,}$ $q_{winter3L,}$ $q_{summer3L,}$ and $q_{autumn3L}$) are estimated by the ASPIC program and not kept constant at the starting guess.
Line 19 and Line 20: minimum and maximum bounds on the estimate of *MSY* (5000-50000 ton) and *K* (100000-500000 ton) respectively. All ASPIC runs on FIT mode gave final estimates of these parameters far from either constraint. The number of bootstrap trials discarded due to parameter estimates falling outside their bounds is minimal.
Line 22: `49` Total number of years in the data sets included in the input file, from 1959 to 2007.

The rest of the settings of the input file were kept with the default options of the ASPIC Ver.5.16. The input file with the formulation used in the assessment, retrospective analysis and projections is presented on Appendix 1.

Exploratory analysis

The 1992 autumn biomass index for Div. 3N and the 1995 autumn index for Div. 3L have anomalously high magnitudes, while staying between relatively low indices from the neighbouring years. The original mean weights per tow have also associated anomalously high errors (highest of each survey series). So survey biomass from these years and divisions were considered outliers of the respective survey series and excluded from the analysis.

Due to the short time overlap between *cpue* and surveys in Div. 3LN combined (1991-2007, 4 years on 49 years of data) the assessment assumes that *cpue* time series, Russian survey and 3L summer and winter surveys basically represent the abundance of the stock during the former period prior to 1990, while 3L autumn survey and surveys in Div. 3LN combined basically represent the abundance of the stock during the more recent period of the 1990's and 2000's. With such a short time overlap, the two pair-wise negative correlations found among STATLANT cpue and the survey series for Div. 3LN combined, each series based on just four pairs of observations, have been disqualified to halt the ASPIC assessment. Therefore only negative correlations between the model and any of the input series of biomass indices, or between surveys overlapping most of the years, were considered a violation of the fundamental assumption of ASPIC that all indices reflect the abundance dynamics of the stock.

Three $ASPIC_{2008}$ formulations, corresponding to three possible arrangements of the alternate Russian and summer in Div. 3L survey series (see table above), were run on FIT mode in order to explore the goodness of fit of the model under three different input survey data:

$ASPIC_{Power,2008}$	I1 (Statlant CPUE)+I2 (3LN spring survey)+I3 (3LN autumn survey)+I4Power (3LN Power russian survey)+I5 (3L winter survey)+I6 (3L summer survey)+I7(3L autumn survey)
$ASPIC_{Power,fullsummer,2008}$	I1 (Statlant CPUE)+I2 (3LN spring survey)+I3 (3LN autumn survey)+I4Power (3LN Power russian survey)+I5 (3L winter survey)+I6 (3L summer survey full series)+I7(3L autumn survey)
$ASPIC_{Vaskov,2008}$	I1 (Statlant CPUE)+I2 (3LN spring survey)+I3 (3LN autumn survey)+I4Vaskov (3LN Vaskov russian survey)+I5 (3L winter survey)+I6 (3L summer survey)+I7(3L autumn survey)

Besides the correlation between alternate Russian and summer series with those which overlap with them, and between ASPIC estimated and observed annual values from each data series (`R squared in CPUE`) other parameters were used as diagnostics of the FIT outputs from the three formulations considered:

- `Number of restarts required for convergence`: The routine used in ASPIC to minimize the objective function can stop at a local minima. In order to find a true minimum of the objective function, which is kept constant regardless the initial values of the key parameters, ASPIC program has a restarting algorithm that requires the same solution to be found several times in a row before it is accepted (Prager, 2005). The shorter the number of restarts the quicker is the convergence the better is the fit of the model to the data series.
- `Estimated contrast index (ideal = 1.0):  C* = (Bmax-Bmin)/K.` A wider contrast on the biomass trajectory reflects wider coverage by the stock exploitation history of the Yield/Biomass curve defined by the ASPIC underlying surplus production model.
- `Estimated nearness index (ideal = 1.0):  N* = 1 - |min(B-Bmsy)|/K.` Being a production model centred on *MSY*, the biomass trajectory given by ASPIC should pass at least once through B_{msy}.
- `TOTAL OBJECTIVE FUNCTION.` Measuring the overall size of the of *cpue* and survey residuals the least squares objective function points out how close model estimates are to observed data.

An overview of the exploratory analysis (Table 6a) lead to the main conclusion that no significant improvement on ASPIC FIT diagnostics is obtained either by using the non documented figures for the Russian survey series (with an extra point on 1993) from Vaskov (1994) or the full series of the summer survey in Div. 3L, which the first four points (1978, 1979, 1981 and 1984) remained unclear if expressed in original Engel or converted Campelen units.

All runs of the three $ASPIC_{2008}$ formulations gave very similar results, both for model parameters (Table 6b) and B/B_{msy} and F/F_{msy} trajectories (Fig. 6a and 6b), framing a very similar picture of the stock:

- Carrying capacity (K) at 263000-285000 ton
- Level of biomass on the 1st year of the assessment higher than B_{msy} (70-73% of K)
- Relatively low rate of stock biomass increase (r), 0.34-0.39
- *MSY* at 24000-25000 ton
- Relatively low F_{msy} , 0.17-0.19
- Fishing mortality on the last year of the assessment (2007) near zero and biomass at the beginning of next year near K
- Very close B/B_{msy} and F/F_{msy} trajectories

The consistency on the outputs between the three formulations left both the lack of references regarding the Russian survey series by Vaskov (1994) and the doubts regarding the units on the first years of summer survey in Div. 3L as the justification for choosing the $ASPIC_{Power2008}$ formulation to pursue with the 2008 assessment. A secondary reason is that this formulation gives a slightly more conservative result in terms of stock dynamics, namely as regards relative biomass trajectory (Fig. 6a). The input file for the selected $ASPIC_{2008}$ formulation is presented as Appendix 1.

<u>Sensitivity analysis</u>

Different starting guesses for key parameters or different random number seeds were used to run the $ASPIC_{Power2008}$ formulation. The purpose was to check if the model was sensitive to changes in the starting "region" of key parameters (or number seed) used to initialize the search of a solution that minimizes the *cpue* and survey log squared residuals. Four starting options were tested against the standard starting option specified on $ASPIC_{Power2008}$ input file (Table 7a):

- 25% above and bellow the default random number seed (Input file, line 21)
- an "optimistic start" given by -25% *cpue* and survey catchabilities together with +25% *MSY, K* and *B1/K*,
- and a pessimistic start given by +25% cpue and survey catchabilities together with -25% *MSY, K* and *B1/K.*

The FIT parameter solutions from each of these four options are compared with the standard FIT solution on Table 7b. The four different starting options arrived to the same or very similar solutions, showing that the ASPIC results given by the selected formulation are robust and independent of the values chosen for the input parameters used to initialize the model.

Retrospective Analysis

A 2008-2004 retrospective analysis with the $ASPIC_{Power2008}$ formulation was carried out in order to check for patterns on bias of relative biomass and fishing mortality estimates. Going back in time the results present an over bias on biomass and an under bias on fishing mortality, but without the typical pattern of increasing bias as each assessment stop one year sooner (Table 8a, 8b and 8c; Fig. 7a and 7b). In fact the upper and lower limit of the analysis (2008-2004) showed similar B/B_{msy} and F/F_{msy} trajectories while the assessments from the last couple of years (2008-2007) fell more apart. The closest results are from the runs of intermediate years (2006 and 2007).

Moreover the largest biases are not found at recent years but through the second half of the 1990's-beginning of 2000's (Fig. 7c). How fast and how far stock biomass recovers after taking off from the depressed level of the mid 1990's is what marks the difference between the assessments included in this retrospective analysis. Not the stock dynamics on the final years, when the difference between biomass and fishing mortality results from sequential assessments tend to smooth as a consequence of a very low level of catches. The consistency of terminal biomass retrospective results will later on be reflected on consistency of medium term projections from consecutive years.

Assessment results

The $ASPIC_{2008}$ formulation runs on both deterministic (FIT) and bootstrap (BOT) mode using 1000 trials. Deterministic results are presented on Appendix 2, with a summary of diagnostics and parameters included on Table 6a and 6b under $ASPIC_{Power,2008}$. Bootstrap results are presented on Appendix 3, with a summary on Table 9. Despite the negative correlations among STATLANT *cpue* and both spring and autumn survey biomass for Div. 3LN combined (conditioned by the very small number of pair-wise observations and not regarded as an assessment constraint), correlation among these surveys is relatively high (r^2 > 0.5). Correlation is high (r^2 > 0.7) among Canadian surveys in Div. 3L and between those and the Russian survey in Div. 3LN The model has a poor fit to either to CPUE or most of the survey data due to the usual wide inter annual variability of redfish abundance indices (Appendix 2). Apart the Canadian spring survey for Div. 3LN combined, where residuals seem to be randomly distributed, negative/positive patterns on residuals between observed and model generated values are present for the rest of the input series. Nevertheless these poor diagnostics seem to have little impact on the consistency of the assessment, taking into account the bootstrap results (Appendix 3 and Table 9): generally small bias of the point estimates (< = 5%) for most parameters. The high level of bias on the absolute and relative (to MSY) equilibrium yield for 2008 is due to a status quo fishing mortality close to zero, leading to a very small equilibrium catch for last year+1. The impact of survey/CPUE residuals on biomass and fishing mortality is minimal as well, with B/B_{msy} and F/F_{msy} bias corrected trajectories practically undistinguishable from their deterministic ones (Fig. 8a and 8b).

The model results suggest a maximum sustainable yield (*MSY*) of 25000 ton (80% CL = 21800, 26600 ton) that can be produced with a fishing mortality of 0.18 (80% CL = 0.12, 0.23) when stock biomass is at B_{msy} level. This magnitude of F_{msy} is consistent with the results of the yield per recruit analysis for redfish in Div. 3LN presented on the 1999 assessment of this resource ($F_{0.1}$ = 0.12, F_{max} = 0.22) (Power and Parsons, 1999). Relative biomass oscillated 13-30% above B_{msy} for most of the former years up to 1987, supporting an average level of catches just bellow MSY (1960-1985 average level of catch at 21000 ton). Apart the 1971-1973 interval, when fishing mortality was at (or slightly above) F_{msy}, fishing mortality oscillated within bounds bellow F_{msy} (35-80%) until 1985. Between 1986 and 1990 catches were higher than *MSY* (29000-79000 ton), pushing fishing mortality to well above F_{msy} from 1986 till 1993. Those eight years of heavy over-fishing determine the fall of biomass from 26% above B_{msy} in 1987 to 35% bellow in 1994, when a minimum stock size is recorded. Long living/slow growing species such as redfish can not sustain over-fishing but for short periods of time: the quick decline of stock biomass through the second half of the 1980's – first half of the 1990's was followed by a drop on catch and fishing mortality. Since 1996 both were kept at low to very low levels. Over the moratorium years biomass was allowed to increase and is now (2007) well above B_{msy} (80% CL = 1.55, 1.96 B_{msy}) (Table 9, Fig. 8a and 8b).

Catch versus surplus production (Appendix 2, ESTIMATED POPULATION TRAJECTORY NON BOOTSTRAPPED, 8th column from the left) trajectories are presented on Fig. 9. From 1960 till 1985 catches form a scattered cloud of points up and down surplus production curve but always within its vicinity. On 1986-1987 catches rise well above the surplus production and though declining continuously since then were still above equilibrium yield in 1993. Estimated catch has been well bellow surplus production levels since 1994.

ASPIC projections

Regardless the input formulations, the starting guess scenario or the mode of the model runs, the main conclusion of this assessment is that at present the biomass of redfish in Div. 3LN is well above B_{msy} , while fishing mortality is well bellow F_{msy} . From ASPIC results the status of the stock allows its exploitation, but this is a first attempt to pursue an analytical assessment of this stock. Therefore these results should be treated with caution.

Underlying assumptions for the low catch option

Redfish in Div. 3LN has been under moratorium over the past ten years. A stepwise approach to direct fishery should start by a low exploitation regime associated with a high probability of keeping the stock biomass within its present safe zone. From the ASPIC bootstrap results (Table 9 and Appendix 3, ESTIMATES FROM BOOTSTRAPPED ANALYSIS, Line 22) this safe zone can be defined as B/B_{msy} = > 1.55, the bias-corrected 80% lower confidence limit of relative biomass at the beginning of 2008.

An ASPIC medium term projection was carried out under constant catch instead of constant fishing mortality. The reason for this option relates to the proposed approach to reopen the fishery keeping the biomass well above $B_{msy,}$, until future assessments confirms a positive answer of the stock to exploitation as suggested by the present assessment. This strategy turns the analysis of medium term projections under a range of F_{msy} percentages useless, since the purpose is to keep a fishing mortality within a low level able to maintain the present stock size.

The catch options for medium term projections should include in principle MSY (25000 ton) and a catch of 21000 ton, a "real world" proxy of MSY corresponding to the average level of catches sustained by the stock over 25 years (1960 -1985). However the purpose of this exercise is not to compare the impact of different full exploitation regimes on the stock but to predict how biomass and fishing mortality react to the beginning of exploitation, just at the actual surplus production level. Therefore ASPIC projection was carried out with a constant catch of 5000 tons. This level of catch is a conservative proxy of the actual equilibrium yield (75% of the bias corrected equilibrium yield for 2008) (Table 9).

The ASPICP program

ASPIC has an auxiliary program, ASPICP, to provide not only bias corrected estimates of biomass and fishing mortality on an annual basis for the assessment time interval (with associated 50% and 80% confidence limits) but also provides projections of these trajectories to the future. ASPICP reads information from the 1000 trials of the BOOTSRAP results kept in a .BIO file and project each of these trials a number of years ahead, under an annual $F_{status\ quo}$ multiplier or yield. These constraints are specified by the user in a .CTL file (Appendix 4) that controls the projection.

The ASPICP run with a 2008 *status quo* catch (2007 level of 1700 ton) and an annual catch of 5000 ton for the rest of the years (2009-2012). Results are stored in a .PRJ file presented in Appendix 5.

<u>Projection results</u>

The bias corrected 1959–2012/ 2013 trajectories of biomass and fishing mortality rate (relative to B_{msy} and F_{msy}.), with associated 80% lower and upper CL's are presented in Table 10a and 10b, Appendix 5 and Fig. 10a and 10b. From the ASPICP results a low exploitation regime of 5000 ton will keep biomass at the same high level, between 1.84 B_{msy} at the beginning of 2008 and 1.87 B_{msy} at the beginning of 2013 (80% CL's, 1.74 -1.91B_{msy}). , Meanwhile fishing mortality will increase from 0.04F_{msy} in 2008 to 0.11 F_{msy} in 2012 (80% CL's, 0.10-0.13 F_{msy}). In other words, a constant catch level of 5000 ton will keep the stock size of redfish in Div. 3LN in its present safe zone, with the lower 80% CL of relative biomass well above the B_{msy} level. At the same time fishing mortality rate will remain at a (very) low level, with an upper 80% CL well bellow F_{msy}.

In order to test if these projection results are robust or if they might be affected by differences on results from previous assessment, the same projection exercise was performed till the same year of 2013, but starting one year earlier (2007). The ASPICP run with the bootstrap results of the 2007 assessment using the same $\text{ASPIC}_{\text{Power}}$ formulation, but for the 1959-2006 interval. A *status quo* catch was adopted for 2007 (= 2006 level of 500 ton) followed by an annual catch of 5000 ton for the rest of the years (2008-2012). The bias corrected 2007-2013 B/B_{msy} trajectories from the two consecutive ASPICP_{2008} and ASPICP_{2007} runs are very similar (Table 11, Fig. 11). Regardless the retrospective bias between the two last assessments both runs shown the stock at the same high level relative to B_{msy} , five-six years after the reopening of a directed fishery at a small scale of 5000 ton.

Reference Points under Precautionary Approach

The ASPIC bias corrected results were input under the precautionary framework (Fig. 12). The stock trajectory presented under this precautionary approach framework shows a stock rapidly declining to bellow B_{msy} when fishing mortality rate rises from just above to well above F_{msy} (1986-1987), and a stock rapidly returning to above B_{msy} after fishing mortality drops to well bellow F_{msy} (1993-1994).

The NAFO SC Study Group recommendations from the meeting in Lorient in 2004 (SCS Doc. 04/12), as regards Limit Reference Points (LRP's) for stocks evaluated with surplus production models, considered F_{lim} at F_{msy} and F_{target} at 2/3 F_{msy}. The Study Group also considered that the biomass giving production of 50% *MSY* was a suitable B_{lim}. Under the Schaeffer model used in the present ASPIC assessment this is 30% B_{msy}. However the stock biomass decline of the late 1980's – early 1990's didn't reach such level, having a minimum at 35% B_{msy}. Taking into account that bellow this level the dynamics of the stock is unknown, a B_{lim}= 35% B_{msy} can be regarded as first attempt to have a biomass LRP for redfish in Div. 3LN.

a Includes catch that could not be identified by division
b includes estimates of unreported catches
c Catch could not be precisely estimate due to discrepancies in figures from available sources: average of the range of the different catch estimates.

Table 2: Redfish STATLANT catch and predicted effort for Div. 3L and Div. 3N, 1959-1994 (Power,1997).
Annual catch rate for Div. 3LN, 1959-1994.

Table 11: Bias corrected B/Bmsy trajectories
from two consecutive ASPIC projections under
a constant catch of 5000 ton

Year	$ASPICP_{2008}$	$ASPICP_{2007}$
2007	1.803	1.894
2008	1.836	1.918
2009	1.862	1.906
2010	1.863	1.901
2011	1.866	1.897
2012	1.869	1.895
2013	1.872	1.896

CONTROL PARAMETERS (FROM INPUT FILE)                                                    Input file: aspic.inp
-----------------------------------------------------------------------------------------------------------------------
Operation of ASPIC:  Fit logistic (Schaefer) model by direct optimization.
Number of years analyzed:                        49            Number of bootstrap trials:                          0
Number of data series:                            7            Bounds on MSY (min, max):       5.000E+03     5.000E+04
Objective function:                   Least squares            Bounds on K (min, max):         1.000E+05     5.000E+05
Relative conv. criterion (simplex):       1.000E-08            Monte Carlo search mode, trials:        0         20000
Relative conv. criterion (restart):       3.000E-08            Random number seed:                             3941285
Relative conv. criterion (effort):        1.000E-04            Identical convergences required in fitting:           6
Maximum F allowed in fitting:                 6.000

PROGRAM STATUS INFORMATION (NON-BOOTSTRAPPED ANALYSIS)                                           error code   0
-----------------------------------------------------------------------------------------------------------------------
Normal convergence

WARNING: Negative correlations detected between some indices.  A fundamental assumption of ASPIC is that all indices
         represent the abundance of the stock.  That assumption appears to be violated.
Number of restarts required for convergence:     47

INFORMATION FOR REPAST (Prager, Porch, Shertzer, & Caddy. 2003. NAJFM 23: 349-361)

Unitless limit reference point in F (Fmsy/F.):	26.38
CV of above (from bootstrap distribution):	0.1544

NOTES ON BOOTSTRAPPED ESTIMATES:

- Bootstrap results were computed from 1000 trials.
- Results are conditional on bounds set on MSY and K in the input file.
- All bootstrapped intervals are approximate. The statistical literature recommends using at least 1000 trials for accurate 95% intervals. The default 80% intervals used by ASPIC should require fewer trials for equivalent accuracy. Using at least 500 trials is recommended.
- Bias estimates are typically of high variance and therefore may be misleading.

Trials replaced for lack of convergence:	0	Trials replaced for MSY out of bounds:	0
Trials replaced for q out-of-bounds:	31		
Trials replaced for K out-of-bounds:	28	Residual-adjustment factor:	1.0535

Elapsed time: 4 hours, 10 minutes, 41 seconds.

Appendix 4:

control file of ASPIC projection 2008-2012

```
'Projection with 5000 Y'   ## Projection title
'aspic.bio'     ## BIO file to read
'red3LN.prj'     ## Projection file to write
0d0                  ## Not used at present; set to 0d0
0                     ## Years to drop at start of plots
5                     ## Years of projections
1700 Y                 ## Specification for projection year 1.
5000 Y                 ## Specification for projection year 2.
5000 Y                 ## Specification for projection year 3.
5000 Y                 ## Specification for projection year 4.
5000 Y                 ## Specification for projection year 5.
```

Note: the years of projection should have on each line:

1. A real number, the projected yield or effort.
   - If yield, it is in the same units as for the initial fit.
   - If effort, it is a unitless number: the multiple of the effort in the last year of the fit.
2. A character*1 indicator of whether the number is effort or yield.
   - This should be the capital letter 'Y' or 'F'.
3. Comments if desired may follow the letter, but must be delimited from it by at least one space.
