## SCIENTIFIC COUNCIL MEETING – JUNE 2007

An assessment of American plaice in NAFO Div. 3LNO

#### Abstract

Catches from this stock were generally in the range of 40,000 to 50,000 t per year throughout the 1970's and 1980's, before declining to low levels in the early 1990's. There has been no directed fishing on this stock since 1993. The TACs in 1995-2007 have been set at 0. Catch has been lower in the two most recent years than in prior years; in 2005 it was 4100 t and in 2006 it was 2800 t, which was mainly taken in the NAFO regulatory area (NRA). The Canadian spring surveys show a large decline in abundance and biomass from the mid to late 1980's to the mid 1990's with the average biomass index of the last 2 years (expressed as mean weight per tow) being only 30% of that of the mid 1980's. The fall survey has also shown large declines and the biomass index is only 36 % of that of 1990. There may be a slight increase in both surveys since the mid 1990's. By Division, the largest decrease in both surveys for biomass and abundance has been in Div. 3L but there has been a slight increase in biomass in Divs. 3LN in the past two years. Mortality on younger (less than 5) ages has remained high throughout the time series. For older ages mortality declined after the mid 1990's but has increased in the last few years on most ages over 6 in both surveys. The 2007 assessment included the Spanish Div. 3NO survey in the VPA analyses which showed that population abundance and biomass declined fairly steadily from the mid 1970's. Biomass has increased slightly in the past few years. F increased fairly steadily from 1995 to 2000 but has generally been declining since then. Average F on ages 9-14 in 2006 was 0.20, the lowest since 1991. Since 2001 the SSB has increased very slightly to 36, 000 t in the current year. This is still only 18% of the level in the mid 1960's and 26% of the level in the mid-1980s. Recruitment has been steadily declining since the 1989 year-class and there have been no good year classes since then. No good recruitment is seen below an SSB of 50 000 t, the B<sub>lim</sub> for this stock.

# **TAC** regulation

This stock has been under TAC regulation since 1973 when a TAC of 60,000 t was established. From 1973-87, the TAC varied from 47,000 t to 60,000 t (Table 1) but was lowered to 33,585 t in 1988. Further reductions followed, bringing the TAC to 10,500 t in 1993. In 1994, a TAC of 4,800 t was implemented, but the Fisheries Commission of NAFO stated that no directed fisheries were to take place on this stock. The TAC has been set at 0 since then.

### Catch trends

Catches increased from about 20,000 t in the early 1960s to a peak of 94,000 t in 1967, were relatively stable around 45,000-50,000 t in 1973-82, then declined to 39,000 t in 1984-85 (Table 1, Fig. 1). Catches increased to 65,000 t in 1986 and then declined rapidly thereafter, to about 7,400 t in 1994. After a decline in catch following the moratorium

in 1995 the catch declined for a couple of years but then began to increase. However in the most recent years catches are lower (4,100 t in 2005 and 2,800 t in 2006), due mainly to a lack of fishing of yellowtail flounder in 2006. In 2005, the Canadian catch totalled about 1,472 t and in 2006, it was only about 94 t. The remainder of the catch occurred as by-catch in the skate, redfish and Greenland halibut fisheries in the NRA.

From 1977 to 1982, the catch was taken almost exclusively by Canadian vessels, but the catch by other nations increased rapidly from less than 2,000 t in 1981-82 to over 30,000 t in 1986 as new fisheries were developed in the Regulatory Area (Table 1). Considerable doubts have arisen about some nominal catches in the 1985 to 1994 period, resulting in various catch estimates being used. These include surveillance estimates, breakdowns of unspecified flounder catches by S. Korea prior to 1991 based on reported flounder catches, and any other estimates deemed by Scientific Council to be reliable. There is also some uncertainty regarding catches prior to 1973, when large amounts of unspecified flounder catches from some nations were broken down by species based on estimates of species composition. As well, estimates of discards are not available, and are believed to be substantial during some periods. In recent years there has been increasing problems in resolving catches in recent years, resulting in variation in estimates.

# Canadian research vessel surveys

#### **Poor Survey Coverage**

During the course of the 2004 Canadian fall and 2006 Canadian spring multi-species survey, operational difficulties lead to incomplete coverage of the survey in NAFO Divisions 3LNO. In fall 2004, the incomplete coverage of the survey series in Div. 3NO were not problematic (Healey and Dwyer 2005). However, several strata not surveyed from Div. 3L were shown to have importance to American plaice. The proportion of the index originating in the missed Div. 3L strata was relatively high (20-50%) (Healey and Dwyer 2005). For Divs. 3LNO as a whole, the proportion of the biomass index sampled in the strata missed in 2004 has been variable but not insubstantial. For ages 2-11, typically between 20-50% of the index has been observed in these strata. Though the percentage of biomass found in Div. 3L has declined in recent years, it still makes up an average of 22% of the total index since 1995.

In spring 2006, some shallow water strata and most deep water strata in Div. 3NO were not completed in the Canadian RV survey. American plaice are found in high numbers (15-30% of Div. 3NO and 13-25% of total index) in these strata. For ages 2-12 for years 2004 and 2005, about 25% of fish are found in these strata. In addition, despite the large increases in numbers, all survey results for spring 2006 are dubious. It is recommended that abundance at age in Divs. 3NO (and Divs. 3LNO combined) not be used in the 2007 assessment. There was no ageing for the spring 2006 survey.

Therefore it was decided to remove both data points from the 2007 assessment. However, because the proportion of strata in Div. 3L as a percent of the total stock area is relatively small, is it recommended that age by age abundance by strata as a percent of the entire index be examined for the 2004 fall survey for the next assessment in order to determine whether this data point should be included.

In this paper, data is included for both data points in shaded columns in tables, in open symbols in figures, and where it is included in analyses, it is noted in the text or captions.

#### **Spring**

Stratified-random surveys have been carried out on the Grand Bank by Canadian research vessels in the spring (April to June period) of each year from 1971 to 2004, with the exception of 1983. The stratification scheme used is shown in Figure 2. The data can be split into 3 time periods, based on the trawl used in each period: 1971-82 was Yankee 36, 1983-95 was Engel 145, and 1996-2004 was Campelen 1800 (see McCallum and Walsh (1996) for a description of the various trawls). Conversions exist for the first to second series (Gavaris and Brodie 1984), and from the second to the third (Morgan et al. 1998). However, data from the first series have not been converted to be comparable with the third series. Thus comparable data exist for 1971-95, and for 1984 to 2004. A full comparison between the Engel and Campelen data series is given in Brodie et al. (1998).

Biomass estimates for each Division by stratum and depth for 1996 to 2006 are given in Tables 3-5. Please note the shaded columns. In 2005, the spring survey biomass estimates for 3L, 3N and 3O were 38, 000, 114, 000 and

53, 000 t respectively. From 1996 to 1998 the estimate for Div. 3N biomass was approximately half of the estimate for Div. 3O while from 1999 to 2004 the estimates in the two divisions are similar. However, in 2005 the biomass estimate from Div. 3N is almost double the biomass estimate from Div. 3O. The biomass estimates in Div. 3L in 2005 is the highest it has been since 1996 (please note the 2006 data point should not be considered as part of this assessment). Biomass in Div. 3LNO combined was the highest it has been since 1996 but is still only 30% of that of the mid 1980's (Fig. 3).

In Figure 4 and 5 the biomass index is shown as mean weight per tow. In Figure 4 the index is presented by division and in Figure 5 for Div. 3LNO combined. Overall the combined index shows the same trend as the swept area estimate of biomass with a large decline in the late 1980s (which has been greatest in Div. 3L) followed by a slight increase since 1996, especially in the last 2 years. The average mean weight per tow in the last 2 years is 23% of the average of the mid 1980's. The increase in mean weight per tow in the past 2 years has been greatest in Div. 3N (Fig. 4).

Figure 6 shows the abundance for Div. 3LNO combined from 1985 to 2006. The total abundance has fluctuated since 1996 with perhaps an increase over the period, especially in the last 2 years. Mean number per tow for Div. 3LNO combined shows the same trend (Fig. 7). As with the biomass estimate, mean number per tow has shown the greatest decline in Div. 3L (Fig. 8).

Tables 5-8 show the abundance at age from the Canadian spring surveys by division and for Div. 3LNO combined. Ageing was not available for spring 2006, and, as mentioned the survey coverage was not adequate. Although the proportion of fish that are ages 0 to 5 was lower in 2004, in recent years has been amongst the highest in the time series. The abundance estimate in 2005 was the highest since 1991 (Table 8).

Figures 9 and 10 show the distribution plots (kg/tow standardized to tow length) of American plaice for 2003-2006. There appears to be an increase in the concentration of American plaice in Div. 3L in the two most recent years. Although still low compared to historic levels, the increase can be seen in the proportion of fish north of 45°N (Figure 11). The largest concentrations of plaice seem to be in Div. 3N outside the 200-mile limit (Figures 9 and 10). The lack of survey coverage can be noted in the 2006 plot.

#### Fall

Stratified-random surveys have been conducted in Div. 3L in the fall from 1981 to 2006, usually in October-November, but in recent years this has been occurring later. From 1990 to 2006, fall surveys were also carried out in Div. 3NO. Surveys from 1983 to 1994 were done with the Engel trawl and starting in fall 1995, a Campelen 1800 trawl was used.

Biomass estimates by stratum and depth are given for each Division in Tables 9-11. Biomass estimates from the fall survey in 2005 were 34, 000, 128, 000 and 59, 000 t for Div. 3L, 3N and 3O respectively. In 2006, the biomass estimates for these Divisions were 58, 000, 120, 000 and 56, 000 t. Over the past number of years, there has been a large biomass estimate in Div. 3N fairly consistently, which is heavily influenced by large sets in stratum 360 (Table 10). During 1995 to 1997, Div. 3N constituted on average 40% of the Div. 3NO total while the average since 2000 has been more than 70% of the Div. 3NO total.

The overall biomass for Div. 3LNO in the fall has shown a slight increasing trend since 1995, levelling off in the past few years (Fig. 3). The biomass index remains well below that of 1990 with the average of the 2005-06 indices representing only 36% of that of 1990. The biomass index expressed as mean weight per tow shows the same overall trend with the average of the last 3 years being 34% of the level of 1990 (Fig. 5). Mean weight per tow has shown the largest decline in Div. 3L (Fig. 12). Mean weight per tow estimates from Div. 3N have increased since 1996, while mean weight per tow in Div. 3O has remained at a low level (Fig. 12).

Figure 6 shows the abundance for Div. 3LNO combined from 1990 to 2006. Abundance showed a substantial decline from 1990 to 1998 but has been stable since 1998. Mean numbers per tow show the same pattern (Fig. 7). By Division, the largest decline was once again in Div. 3L (Fig. 13) but increases were shown in both Division 3N and 3O. There was a large increase in mean numbers per tow in Division 3O; the 2004 value was the highest in the time series (Fig. 13).

Tables 12-15 show the abundance by age for 1990 to 2006. Abundance in Div. 3L declined in each year since 1995 to 2000 but increased in 2001 and has remained at that level ever since (with the exception of 2004, which was poorly covered by the survey). The age composition has seen younger ages making up a higher proportion of the population in the last few years and a small increase in the number of older fish since 1999 (Table 15).

Plots of distribution by weight (Fig. 14) for the fall surveys for 2005-2006 show that A. plaice are distributed throughout the Div. 3LNO area. However the area of highest concentration is southern 3NO, particularly on the tail of the bank in Div. 3N. Note the lack of coverage in Div. 3L in 2004.

### **Comparison of Spring and Fall Surveys**

Biomass and abundance from the spring and fall surveys can be seen in Figures 3 and 6. In the most recent years, abundance in spring and fall show opposing trends (Figure 6), possibly due to survey timing changes and fish moving into and out of the survey area. Historically, both surveys have shown the largest decline in Div. 3L. There are some larger catches off the Grand Banks in Div. 3L in the fall but overall, distribution is also similar between the two surveys, with the majority of the fish being distributed in southern Div. 3NO (Figs. 9, 10 and 14).

#### Catch to RV Biomass ratio

In 2000 STACFIS recommended that *in future catch to survey biomass plots be presented*. Therefore, as a proxy for fishing mortality on this stock, the ratio of catch to biomass from spring RV surveys was examined. Examination of the catch/biomass ratios from Campelen data from 1985 to 2006 is shown in Figure 15. The Campelen ratios were highest in the 1991-94 period, and were reduced from 1995-1999, reflecting a period of reduced catches (Table 1). The catch/biomass ratios increased substantially over the 1999 to 2004 period, but were lower again in 2005 and 2006.

### Mortality

Estimates of total mortality (Z) from the Campelen or equivalent, spring and fall survey data were calculated for ages 1 to 16 (Fig. 16 and 17). A Lowess smoother with a smoothing window is plotted to help illustrate trends. The spring survey indicates an increase in mortality up to the mid 1990's for most ages. This trend is also evident in the fall data but is not as apparent. Mortality declined after the mid 1990's in both surveys but has shown some slight increase in the last few years in the spring survey, although the last estimate is lower in most ages. In the fall, there is a decreasing trend in Z in the last few years which is driven mainly by two lower points in 2004 and 2005 (ie from 2004 to 2005 and 2005 to 2006). There are no estimates for 2005 in the spring due to the incomplete coverage of the 2006 spring survey; however, the fall 2004 survey data is included.

# Weights and lengths at age

Mean weights-at-age were calculated for male and female American plaice for Div. 3LNO using spring survey data from 1990 to 2005. Mean lengths-at-age were calculated using data from 1985 to 2005. Means were calculated accounting for the length stratified sampling design. There is little indication of trend over the time period in either mean length or mean weight (Fig. 18 and 19). However, ages 6, 8 and 10 for females have shown some increase in mean length and weight since about 1999.

#### **Maturities**

Age and length at 50% maturity were produced from spring RV data. Maturity data were collected during research vessel surveys from 1960-2006. Stratified random surveys were used where possible (1971-2006). Data from earlier years came from surveys that were conducted mainly as line transects. The coverage of a stock area would generally not be as complete as the stratified random surveys. For the period of the stratified random surveys, observed proportion mature at age was calculated according to the method of Morgan and Hoenig (1997) to account for the length stratified method of sampling. Prior to this, only data from the aged fish was used without weighting by the length frequencies. This should not have a large impact on the model estimates (Morgan and Hoenig 1997). Data from 1985-1995 were converted to Campelen equivalents.

Estimates were produced by cohort. For males,  $A_{50}$  were fairly stable for cohorts of the 1960's to mid 1970's, with perhaps a slight increase over that time period. Male  $A_{50}$  then began a fairly steady decline to the 1991 cohort which had an  $A_{50}$  of just over 3 years. Male  $A_{50}$  has increased somewhat but is still below the 1960's and 1970's with an  $A_{50}$  of about 4 years compared to 6 years at the beginning of the time series (Fig. 20). For females, estimates of  $A_{50}$  have shown a large, almost continuous decline, since the beginning of the time series. For females the  $A_{50}$  for recent cohorts is about 7 years compared to 11 years for cohorts at the beginning of the time series.

Estimates of maturity at length were produced using the data described above and are presented by cohort in Figure 21.  $L_{50}$  declined for both sexes but recovered in recent cohorts. The current  $L_{50}$  for males of about 20 cm is similar to the earliest cohorts estimated. The  $L_{50}$  of most recent cohorts for females is in the range of 34-36 cm, somewhat lower than the 39 cm of the earliest cohorts.

## Spanish Div. 3NO survey

Numbers at Age

Since 1995, Spain has carried out a random stratified spring bottom trawl survey in Div. 3NO of the NAFO Regulatory Area. In 2001, the trawl vessel (C/V Playa de Menduiña) and gear (Pedreira) were replaced by the R/V Vizconde de Eza using a Campelen trawl. Canadian spring RV age length keys (for Div. 3N only, as the Survey by Spanish Div. 3NO survey only covers a small portion of Div. 3O) were applied to Spanish length frequency data (separate sexes, mean number per tow) from 1997-2000 converted data and 2001-2006 Campelen data (González Tronosco et al., 2006, 2007). Combined spring Canadian ALKs from 1997-2005 were applied to the 2006 length frequencies. This data is found in Table 25 and was used in the final VPA run of 2007. The age composition for this survey was similar to the Canadian RV spring survey.

#### Catch at age

Results of the catch at age calculations for American plaice catches in 1993-2006 are given in detail in Morgan et al. (1999a,b; 2001a; 2002, 2003,) and Dwyer et al (2005). In 2005 and 2006, sampling data were available from by-catch of A. plaice in Canadian fisheries targeting other species in Div. 3LNO. As has been the case since it reopened in 1998, much of the Canadian sampling data in 2005 came from observer coverage in the yellowtail fishery. In 2006, there was virtually no fishery for yellowtail, and some sampling was available from the relatively small by-catch in the fishery for 3O redfish.

Total Canadian catch of A. plaice in 3LNO in 2005 was 1464 tons, which was 169 tons higher than in 2004. Ninety-seven percent (97%) of the catch came from the directed fishery for yellowtail flounder in Div. 3LNO. In 2006, the Canadian catch of A. plaice was only 92 (actually 94 tons but calculations made to 92 t) tons, due to an almost complete halt to the Canadian yellowtail flounder fishery due to labour problems in the main harvesting company. This relatively small quantity of A. plaice came mainly as by-catch in the redfish fishery in Div. 3O.

Since the beginning of 2000, fishing for yellowtail has been permitted in Div. 3L, resulting in some by-catch of American plaice there, although most (69%) of the catch in 2005 came from Div. 3N, as in the previous years. In 2005, 53% of the Canadian catch occurred in April to June, compared to about 66% in 2004. By-catch of A.plaice in the yellowtail fishery has usually been higher in this period. Catches are lower during the summer as there has usually been a closure of the yellowtail fishery during mid June to late July, which is intended to cover the spawning period for yellowtail. Most of the small catch of A. plaice in 2006 occurred in Div. 3O in January and February (Tables 16 and 17).

Sampling of the Canadian catch of A. plaice in 2005 consisted of 27,782 length measurements, from all months except July and August, and 2127 otoliths. These sampling levels were lower than 2004 for length data and similar for otoliths, and reflect the first full year where observer coverage < 100% was allowed. (In 2004, 37,140 length measurements were collected, along with 2333 otoliths). In 2006, 1 length frequency, consisting of 282 measurements was collected, and no otoliths were taken.

The same weight-length relationship was used as in recent years (log weight = 3.3247 log length - 5.553) and the sum of products check in 2005 was within 3% of the catch. The Canadian catch in 2005 consisted of about 1.89 million A. plaice, which was in the range of the 2003 and 2004 catch numbers. The catch ranged from age 4 to 20, and was comprised mainly of fish aged 7 to 11 years old, with a peak at age 7. The peak age in the catch numbers has declined from 9 or 10 in 1999-2001 to age 8 in 2002-03 and to age 7 in 2004-05. Age 6 comprised about 7% of the catch numbers in 2004, compared to about 20% for this age in 2004. Overall, the catch at age in 2005 was similar to that calculated for 1999-2004, as well as that from the Canadian fishery for A. plaice on the Grand Bank in the early 1990's (Brodie et al. 1994).

To allow an estimate of catch at age in 2006 to be calculated, an age length key from 2005 was applied to the length frequency data. Catch at age was similar to other years, with most of the numbers occurring at ages 7-11. However, the catch at age and weight at age for 2006 should be treated with caution, and will not be discussed here in detail.

The mean fish weight in the 2005 catch was 0.751 kg., up from 2003 and 2004 (0.713 and 0.716 kg.), and continued the increasing trend in recent years. Individual weights at age in 2005 were within the range of values observed from 2002-2004, but lower in 2005 than in 2004, thus ending an increasing trend in recent years (Tables 18 and 19).

For 2005 length frequency data were available from Russia and Spain and for 2006, length frequency data were available from Portugal, Russia and Spain. Details on the sampling levels and descriptions of the fisheries are contained in Vaskov et al. (2005, 2006), González et al. (2005, 2006) and Vargas et al. (2005, 2006). In all cases, age-length keys from the Canadian spring surveys in Div. 3LNO in 2005 (due to poor coverage from 2006 survey) was used to derive age compositions, which were then combined and adjusted to the total catch to account for all non-sampled catches. Catch at age, weight at age (using the weight-length relationship used above) and sum of products (SOP) for 2005 and 2006 are given in Table 20 and 21.

In 2005, catch from all countries indicated a large peak at age 7 -11. In 2006, age 7 was still the most abundant age in Russian catch, but there also seemed to be some older fish in the catch, as there were also large catches made up of fish up to age 14 in other countries. Mean lengths and weights at age in the Canadian fishery were slightly higher at younger ages than in international catches, likely a result of larger mesh size used in the Canadian fishery and also the use of research vessel age-length keys for the catches of non-Canadian fleets.

# Virtual Population Analysis (VPA)

STACFIS previously recommended that several exploratory analyses of the ADAPT model using alternative datasets and model formulation be evaluated as well as a further comparison of trends between the Canadian spring survey and Spanish Div. 3NO survey (NAFO, 2005). After some exploratory analyses, it was decided that shortening or splitting the tuning index does not improve the residual pattern and concluded that the Spanish Div. 3NO survey would be added to the current ADAPT model with the caveat that the inclusion of this index be examined periodically to ensure it continues to track the index especially if the status of the stock begins to improve in Div. 3L (Dwyer et al., 2007).

Standardized age by age abundance (using mean and standard deviation of each index) was plotted using an exploratory data analysis package, Fisheries Library in R (FLR; <a href="www.flr-project.org">www.flr-project.org</a>) for all Canadian surveys (Engels and Campelen) and compared with Spanish Div. 3NO survey (Dwyer et al., 2007; Fig. 22). Surveys seemed to show the same trends in abundance at age, somewhat less at older ages. The Spanish Div. 3NO survey showed slightly higher estimates of the 1998 cohort at ages 5 and 6, relative to estimates of these cohorts in the Canadian surveys at these ages.

A formulation of ADAPT using the same base structure that was used in the accepted VPA since the 2001 assessment (Morgan et al 2001a, 2002, 2003; Dwyer et al., 2005) was run. The ADAPT used catch—at-age for ages 5 to 14 with an age 15 plus group which included all catch from ages 15 to 21 (Table 23). The ratio of F on the plus group to F on the last true age was set at 1.0. M was set at 0.2 except at 0.53 for all ages from 1989 to 1996 (Morgan and Brodie, 2001). Beginning of the year weights-at-age and maturities-at-age are given in Tables 24 and 25. The calibration matrix consisted of the following:

- Canadian spring RV survey (1985-2005) abundance at age (ages 5-14);
- Canadian autumn RV survey (1990-2003) abundance at age (ages 5-14);
- Canadian autumn RV survey (2005-2006) abundance at age (ages 5-14); and
- Spanish Div. 3NO survey (1998-2006) MNPT (ages 5-14) (Table 22a, b, c).

A small error in abundance at age was discovered in the Canadian RV spring 2003 and 2004 estimates for Divs. 3LNO as well as an error in 2003 in Canadian RV fall survey. The errors were slight and when a comparative run (with the 2005 assessment numbers) was attempted with ADAPT differences were minimal. The assessment using the correct numbers gives a somewhat higher estimate of recruitment (36612 vs. 31112 t in most recent year).

The results of an ADAPT run using the formulation described above are given in Table 26 and Figures 23-26. The model provides a good fit to the data. The mean square of the residuals was 0.28. Relative errors on the population estimates ranged from 0.19 to 0.34. The relative errors on the catchabilities (q) were all less than 0.2. The residuals from the Canadian spring survey showed an increasing trend in more recent years; the Canadian fall survey showed no major patterns. The residuals from the Spanish Div. 3NO survey were smaller than the residuals from the other two surveys with little pattern (Fig. 23). There is some tendency for there to be a lag between the predicted and observed survey estimates at age for the fall survey but a better fit for the spring survey. The fit of predicted and observed survey estimates is not a good fit for the Spanish Div. 3NO survey (Fig. 24). Residuals are larger for the older ages in the fall survey but are fairly low overall (Fig 25). Survey qs showed that q is lower for the youngest fish and also older fish but is fairly constant across age (Fig. 26). Qs from the Spanish Div. 3NO survey show a different pattern than the other surveys and may catch a larger proportion of older fish.

Population numbers and F from this run are shown in Tables 27 and 28. Biomass was calculated by multiplying the population numbers at age by the beginning of the year weights at age. The VPA analyses showed that population abundance and biomass declined fairly steadily from the mid 1970's. Biomass has been relatively stable over the last number of years (Fig. 27), increasing slightly in the last three years. Average F on ages 9 to 14 and ages 11 to 14 showed an increasing trend from about 1965 to 1985. There was a large peak in F in 1993, which may be an artifact. F since 1995 has been generally lower than in the earlier period but increased fairly steadily from 1995 to 2000. F has been slightly lower since then. Average F on ages 9-14 in 2005 was 0.32 and in 2006 was 0.24 (Table 28, Fig. 27).

Spawning stock biomass was calculated by multiplying the biomass at age by the female maturity ogive (Table 25). SSB has shown 2 peaks, one in the mid 1960's and another in the early to mid 1980's. Since then it declined to a very low level (less than 10 000 t) in 1994 and 1995 (Figure 28, Table 29). Since 2001 the SSB has increased slightly to 36, 000 t in the current year. This is still only 18% of the level in the mid 1960's and 26% of the level in the mid-1980s. The stock recruit scatter is also shown in Figure 28. Recruitment has been steadily declining since the 1986 year-class and there have been no good year classes since then. An examination of the stock recruit scatter shows that there has been only good recruitment observed above 155 000 t and no good recruitment observed at SSB below 50 000 tons (Fig. 28). This level of 50 000 tons has been taken as a B<sub>lim</sub> for this stock. The most recent cohort still falls below this level.

A retrospective analysis was conducted by sequentially removing one year of data from the most recent year to 2003 for a comparison of 5 years. The results of this analysis are shown in Figures 29 to 31 and Tables 30 and 31. The magnitude of the retrospective revisions in the current assessments has increased compared to past assessments. There is evidence of a retrospective pattern when examined for population abundance in total (Fig. 29) especially in the younger ages when examined on an age by age basis (Fig. 31). A retrospective pattern is also evident for average F estimates starting in 1995 (Fig. 30). The retrospective pattern may be due in part to higher estimates of the 1998 cohort from the Spanish Div. 3NO survey at ages 5 and 6, relative to estimates of these cohorts in the Canadian surveys at these ages. This can also be seen in the retrospective matrix (Tables 30 and 31) in the ratios for the 1998 cohort that are different than +/- 10%.

#### **Medium Term Projections**

Deterministic projections were carried out for 5 years to examine the trajectory of the spawning stock biomass under 2 scenarios of fishing mortality: F = 0,  $F = F_{current}$ . For these deterministic projections the results of the VPA were used.  $F_{current}$  was set as the average F on ages 9-14 over the last 3 years and was 0.31. PR and weights

were averaged over the last 3 years. Recruitment was the average R/S for the last 3 year-classes and was equal to 2.43. In addition the following values were used for 2008-2012:

| Age          | 5    | 6    | 7    | 8    | 9    | 10   | 11   | 12   | 13   | 14 15 | +    |
|--------------|------|------|------|------|------|------|------|------|------|-------|------|
|              |      |      |      |      |      |      |      |      |      |       |      |
| M            | 0.20 | 0.20 | 0.20 | 0.20 | 0.20 | 0.20 | 0.20 | 0.20 | 0.20 | 0.20  | 0.20 |
| PR           | 0.01 | 0.06 | 0.16 | 0.34 | 0.69 | 0.87 | 1.00 | 0.94 | 0.93 | 0.85  | 0.85 |
| Stock Weight | 0.15 | 0.26 | 0.38 | 0.48 | 0.58 | 0.70 | 0.86 | 0.99 | 1.21 | 1.50  | 1.93 |
| Maturities   | 0.03 | 0.15 | 0.46 | 0.81 | 0.95 | 1.00 | 1.00 | 1.00 | 1.00 | 1.00  | 1.00 |

The stock is estimated to increase under both  $F = F_{current}$  and F = 0, with the increase in SSB at F=0 double that at current F. The increase under current conditions of F is only about 12 000 tons over the 5 year period and the stock does not exceed  $B_{lim}$ . The spawning stock reaches the  $B_{lim}$  of 50 000 tons by 2009 and 83 000 tons by 2012 with F = 0 (Fig. 32).

Values for countries back to 2000 are provisional.

<sup>&</sup>lt;sup>a</sup>May include some catch estimated from surveillance reports or miscellaneous information. See text for details.

<sup>&</sup>lt;sup>b</sup> Catch may have been as high as 19,400.

<sup>&</sup>lt;sup>c</sup> Effective TAC.

d No directed fishing.

<sup>&</sup>lt;sup>e</sup> STACFIS unable to determine precise estimates because of discrepancies between various sources.

Table 2 . Biomass estimates ('000t) of A.plaice, by stratum and depth zone (m), from Canadian spring surveys in Div. 3L in 1996-2006 (Campelen). (+) indicates biomass <50 t, (-) means stratum not surveyed.

Table 9. Biomass estimates ('000t) of A.plaice, by stratum and depth zone (m), from Canadian fall surveys in Div. 3L in 1995-2006 (Campelen). (+) indicates biomass <50 t, (-) means stratum not surveyed.

Figure 1. American plaice catches ('000 tons) from 1960 – 2006 (A) and since the moratorium (1995-2006) (B).

Figure 2. Stratification scheme used in Canadian research vessel surveys of Div. 3LNO.

Figure 3. Biomass ('000 tons) of American plaice from spring and fall Canadian surveys in Div. 3LNO combined. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 4. Mean (± 1 Std. dev.) weight per tow (Kg) of American plaice from Canadian spring surveys inDiv. 3L, 3N and 3O. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 5. Mean weight per tow (± 1 Std. dev.) of American plaice from Canadian spring and fall surveys of Div. 3LNO combined. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 6. Abundance (millions) of American plaice from spring and fall Canadian surveys in Div. 3LNO combined. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 7. Mean ( $\pm$  1 Std. Dev.) number per tow of American plaice from Canadian spring and fall surveys of Div. 3LNO combined. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 8. Mean ( $\pm$  1 Std. Dev.) number per tow of American plaice from Canadian spring surveys of Div. 3L, 3N and 3O. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 9. Distribution of American plaice (kg per tow) from Canadian spring surveys in NAFO Divisions 3LNO from 2003-2006. Note survey coverage in 2006 in Div. 3NO.

Figure 10. Distribution of American plaice (kg per tow) from Canadian spring surveys in NAFO Divisions 3LNO in 2005 and 2006. Note survey coverage in Div. 3NO.

Figure 11. Biomass estimates of American plaice, from Canadian spring surveys in Div. 3LNO. Data are shown in relation to 45 degrees North latitude.

Figure 12. Mean (± 1 Std. Dev.) weight (Kg) per tow of American plaice from Canadian fall surveys in Div. 3L, 3N and 3O. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 13. Mean ( $\pm$  1 Std. Dev.) number per tow of American plaice from Canadian fall surveys of Div. 3L, 3N and 3O. Note that open symbol represents years when survey coverage was poor and are not included in 2007 assessment.

Figure 14. Distribution of American plaice (kg per tow) from Canadian fall surveys in NAFO Divisions 3LNO for 2005 and 2006.

Figure 15. Total catch from 1985 to 2005 and the catch/biomass ratio for the same period.

Figure 16. Estimates of mortality for ages 1 to 16 from Canadian spring surveys from 1985 to 2005.

Figure 17. Estimates of mortality for ages 1 to 16 from Canadian fall surveys from 1990 to 2006. Note that fall 2004 is included.

Figure 18. Mean length at age for selected ages of Div. 3LNO American plaice from Canadian spring RV surveys.

Figure 19. Mean weight at age for selected ages for male and female American plaice in Div. 3LNO from Canadian spring RV surveys.

Figure 20. Age at 50% maturity ( $\pm$  95% fiducial limits) by cohort for male and female American plaice in NAFO Divs. 3LNO.

Figure 21. Length at 50% maturity ( $\pm$  95% fiducial limits) by cohort for male and female American plaice in NAFO Divs. 3LNO.

Figure 22. Standardized age by age abundance between surveys (FLR). Note data from Canadian Fall RV survey 2004 is included.

Figure 23. Residuals by year and month (numbers represent ages) for Canadian fall survey (top left), spring survey (top right) and Spanish Div. 3NO survey (bottom). Filled circle is the mean annual residual. Note the scales are different for each plot.

Figure 24. Observed versus predicted abundance for fall and spring indices over time.

## 3LNO American plaice

Figure 25. Mean squared residuals by age for fall, spring and Spanish Div. 3NO surveys.

Figure 26. Bottom panel shows the survey catchabilities (q) for each survey by age. Please note Spanish Div. 3NO survey in mean numbers per tow at age, other surveys abundance at age.

Figure 27. 5+ biomass and abundance (top) and average fishing mortality on ages 9 to 14 and ages 11 to 14 (bottom) from VPA.

Figure 28. Observed stock recruit scatter. Vertical line illustrates Blim.

Figure 29. Results of retrospective analysis for Div. 3LNO American plaice. Top panel shows 6+ population abundance for the whole time period while the bottom panel shows only the time period from 1989.

Figure 30. Results of retrospective analysis for Div. 3LNO American plaice. Average fishing mortality over ages 9 to 14.

Figure 31. Results of retrospective analysis for Div. 3LNO American plaice. Population numbers (millions) for selected ages.

Figure 32. Estimated spawning stock biomass in medium term projections at current F=0. The vertical line indicates the start of the projection period. The horizontal line in the top panel gives the  $B_{lim}$  of 50 000 tons. The top panel shows the period of the projection along with the historic time series, the bottom panel shows only since 1994.
