Abstract

The quota for NAFO Division 4X/5Y haddock has remained at 8,100t for the last 5 years. Reported landings have been close to the quota each year. The quota in 2003 is 10,000t. Abundance has been increasing since the early 1990s and is presently near the high levels observed in the late 1970s. Size-at-age and growth have decreased since 1970, particularly at older ages. Exploitation rate for ages 5-7 decreased from approximately 50% in the early 1980s to below 20% (corresponds to currently used F_{0.1}=0.25) since 1994. Partial recruitment has changed in recent years and fully recruited ages have changed from 5-7 to 8-10. Exploitation on fully recruited ages (8-10) has remained high at about 20%. The 1998 yearclass is estimated to be the largest observed in the time series, and the 1999 yearclass is estimated to be very large; however due to the retrospective pattern these yearclasses may be substantially over-estimated. Spawning stock biomass (ages 4+) is estimated to increase to a high in 2004 and then decrease subsequently unless further strong recruitment occurs. Projected yield at $F_{0.1}$ in the 2004 fishing year is estimated to be 11,000t; however due to the retrospective pattern, this may also be over-estimated. Emphasis should be on how the potential yield from the current good recruitment is to be utilised over time. The catch of cod in the mixed groundfish fishery is a concern and conservation of cod should be considered in the management plan for this fishery.

<u>Résumé</u>

Le quota pour l'aiglefin des divisions 4X/5Y de l'OPANO se chiffrait à 8 100 t pour chacune des cinq dernières années et les prises annuelles signalées se rapprochaient du quota. Le quota pour 2003 a été fixé à 10 000 t. L'abondance est à la hausse depuis le début des années 1990, se situant actuellement près des pics observés à la fin des années 1970. La taille selon l'âge et le taux de croissance ont diminué depuis 1970, en particulier chez les individus âgés. Le taux d'exploitation des âges 5 à 7 a diminué, passant d'environ 50 % au début des années 1980 à moins de 20 % (taux correspondant au F0,1 = 0,25 actuellement utilisé) depuis 1994. Le recrutement partiel a changé dans les dernières années et les âges pleinement recrutés sont passés de 5 à 7 à 8 à 10. Le taux d'exploitation des âges pleinement recrutés (8-10 ans) est encore élevé, se situant à environ 20 %. La classe d'âge 1998 est considérée comme la plus abondante de la série chronologique et celle de 1999 très abondante, mais à cause du profil rétrospectif, il se peut que leurs effectifs soient considérablement surestimés. On prévoit que la biomasse du stock reproducteur (individus de 4 ans et plus) atteindra un pic en 2004 puis diminuera par après à moins qu'un recrutement important se manifeste. Le rendement prévu de la pêche à F0,1 en 2004 devrait atteindre 11 000 t, mais à cause du profil rétrospectif, ceci pourrait aussi être une surestimation. Comment utiliser au fil du temps le rendement potentiel du bon recrutement actuel devrait être un objectif de gestion. La capture de la morue lors de la pêche mixte du poisson de fond étant une préoccupation, il faudrait tenir compte de la conservation de l'espèce dans le plan de gestion de cette pêche.

Introduction

This document contains an evaluation of the haddock stock on the southern Scotian Shelf and Bay of Fundy (NAFO Division 4X). As in previous assessments of this stock (Hurley et al. 2002, 1999), haddock caught by Canadian fishermen in NAFO Division 5Y are included in the management unit. Haddock in the Bay of Fundy area grow faster than haddock on the southern Scotian Shelf. As a result, haddock landings from 4Xmnop and 4Xqrs5Y are handled separately and separate age/length keys are used for landings from the two areas, designated as Scotian Shelf and Bay of Fundy stock components respectively (Figure 1). Similarly haddock catches from the summer research vessel survey strata 470-481 and 482-495 are handled separately, as Scotian Shelf and Bay of Fundy components. In 1999, the fishing year changed from January to December to April to March.

Quota management was introduced for this stock by ICNAF in 1970 and a seasonal spawning closure of Browns Bank was instituted that same year. The current closure extends from February 1 to June 15. The history of this area closure is documented by Halliday 1988.

This assessment includes the summer research vessel survey data from the current year, together with commercial landings data for the first half of the year and port samples of those landings, to determine stock status in the current year and make yield projections for the fishing year 2004-05. The results of an industry survey were also used in the assessment.

The Fishery

The long-term (1948-2002) reported annual landings of haddock in NAFO Division 4X/5Y average about 18,000t. Landings exceeded 30,000t during the mid- to late 1960s and again during the early 1980s (Table 1 and 2, Figure 2). Landings declined subsequently and have been below the long-term average since 1984. Landings reached 6,800t in 1989 when it was recommended that the fishery be maintained at the lowest possible level and the mobile gear fleet was closed in mid-season. Landings increased from 1989 to exceed 10,000t in 1992 under a Management Plan that called for a by-catch fishery only. Landings in 1994 were 4,406t, the lowest level in recent history, under a quota of 4,500t and stringent fishing plans. Quotas have not been exceeded since then. The TAC of 8,100t established for the 12-month fishery in 1999 was extended to 9,800t for the 15-month period ending March 31, 2000, based on the proportion of landings in the first quarter of the year over the previous 10 years. The fishing year since then has been April 1 to March 31. The quota remained at 8,100t for the next 3 years and landings have been close to the quota. The quota in the 2003/4 fishing year was initially set at 8,100t but was increased to 10,000t in September 2003.

The fishery was dominated by the mobile gear sector between 1977 and 1989 (Table 3). Between 1990 and 1994, the fixed gear sector took a larger proportion of the landings; however the proportion taken by the mobile gear sector has increased since and was 71% in 2002 (Table 4, Figure 3). Fixed gear landings are primarily from longlines. Landings by handlines have been small and have been declining since 1994.

Several recent changes to the management of this fishery have had a significant impact on the timing of the fishery. As a result of the change to an April-March fishing year in 2000, haddock landings in the first quarter (January-March) of 2000 and 2001 were the highest since 1992 (Table 4a, Figure 4). Landings in the first quarter of 2002 and 2003 were also high. Both the fixed gear

and mobile gear sectors indicate this is due primarily to the ability to direct for haddock with a minimal bycatch of cod at that time of year.

This change in timing of the fishery has also led to changes in the distribution of catches. The proportion of catches coming from 4Xn and 4Xp has been increasing in recent years (Table 4b, Figure 5). While the increase in 4Xn is largely a result of the increase in the winter fishery, the increase in catches in 4Xp reflects directing for larger haddock in deeper water, which generally returns higher market value and also is an area in which the bycatch of cod is relatively low.

Nominal landings of 4X/5Y haddock in the fishing year ending March 31, 2003, were 7,964t relative to a quota of 8,100t. The 2003 fishing year is progressing more slowly than last year (Table 4 and 5, Figure 6 and 7). Haddock landings from April to September were down 9% from the same period last year, while cod landings were down 20%. Groundfish landings overall were down 25% (11% if silver hake and dogfish are excluded). Some of this delay is due to the abundance of dogfish in 2003, particularly in eastern 4X. Low fish prices and uncertainty regarding the mid-season increase in the haddock quota also contributed to this delay.

Reports from industry indicate that haddock abundance has been good throughout the stock area in recent years although there were reports of changes in inshore distribution in the last year or two. Catches of small fish have been prevalent, particularly in eastern 4X. Reports indicate that discarding and misreporting of 4X/5Y haddock have been minimal in recent years.

Data

Age Composition of the Catch

Port samples of landings were used to construct a catch-at-age for 2002 and the first half of 2003 as in previous assessments of this resource. The age composition was derived by application of age/length keys to length frequencies, stratified by quarter and gear. Due to differences in growth rates between haddock on the Scotian Shelf and in the Bay of Fundy, landings are separated into 4Xmnop and 4Xqrs5Y and separate age/length keys were used, whenever possible. Seasonal length/weight parameters derived by O'Boyle et al. (1983) were used. When insufficient samples were available to satisfy the stratification, length frequencies were aggregated and a common age/length key was applied. In some cases, a key from one gear, quarter or area was applied to another where no otoliths were available. The gear and quarter aggregations are shown in Table 6 and 7.

As a routine check, the primary ager reads the 4X haddock otolith reference collection. A pair-wise comparison of ages showed high precision and little bias, with an overall coefficient of variation of 1.1% (Figure 8). These results were considered acceptable.

The resulting catch-at-age is shown in Table 8 and the age composition for 1996-2003 is shown in Table 9 and Figure 9. The 1998 yearclass began to recruit to the fishery in 2001. At age 4 in 2002, it made up 35% of the catch by weight. The 1999 yearclass began to recruit to the fishery in 2003 and made up 24% of the half-year catch by weight. The 1998 yearclass made up 37% of the half-year catch.

Mean weights-at-age in the commercial landings have been variable with a modest decline since the early 1990s (Table 10, Figure 10). The age 5 and younger weights-at-age in recent years are similar

to those in the 1970s but ages 7 and older are very low compared to the late 1970s and early 1980s. Similar declines in weights-at-age have been observed for haddock on the eastern Scotian Shelf (Mohn and Simon 2002, Frank et al. 2001).

As the 1998 and 1999 yearclasses dominate the fishery, the proportion of small (<43cm) haddock in the catch has increased, particularly in the winter fishery (Figure 11-13). The proportion of small haddock in landings from 4Xmnop in the first quarter of 2003 was 24% and 38% for otter trawl and longline landings respectively.

Research Vessel Surveys

A summer groundfish research vessel (RV) survey of the Scotian Shelf and Bay of Fundy has been conducted since 1970. The stratification scheme used in the stratified random survey design is shown in Figure 14. A vessel conversion factor of 1.2 was used for the *A.T. Cameron* surveys (Fanning 1985). Catches from the 2000-2002 surveys are shown in Figure 15. Mean numbers per standard tow by stratum are shown in Table 11.

Stratified mean number per standard tow of 4X/5Y haddock declined in 2002 from the high levels observed in 1999-2001 and declined again in 2003 but was still above the long-term mean (Table 11, Figure 16). Stratified mean weight per standard tow increased in 2003 and was above the long-term mean (Figure 16). Catches in the Scotian Shelf component (strata 470-481) have declined in recent years while catches in the Bay of Fundy (strata 482-495) remained relatively stable (Table 11, Figure 17).

Stratified mean numbers-at-age per standard tow for the 1970-2003 summer RV surveys are shown in Table 12 and the age composition of the RV survey catches from 1996-2003 are shown in Figure 18. The above average 1993 and 1994 yearclasses are apparent. Catches of the 1998 and 1999 yearclasses were very large and 2000 yearclass was above the long-term mean. The 2001 and 2002 yearclasses were well below the long-term mean.

The biomass of ages 4+ haddock in the RV survey, a proxy for spawning stock biomass, has shown an increasing trend since 1993 and in 2003 was near the high levels observed in the late 1970s (Figure 19). The 1998 and 1999 yearclasses made up approximately two-thirds of the 4+ biomass in 2003. The proportion of the 4+ biomass on the Scotian Shelf has shown an increasing trend but decreased and was close to 50% in 2003 (Figure 19).

The catch per tow of ages 2 and 3 in the summer RV surveys, adjusted by the calibration coefficients from the SPA, an indicator of recruitment, was below average from 1983 to 1992, with the exception of the 1987 and 1988 yearclasses. The 1993 and 1994 yearclasses were strong. The 1998 yearclass was the largest in the RV survey series and the 1999 yearclass was the third largest. The 2000 yearclass was above the long-term mean.

The age structure of a population reflects the quality of the population abundance. In general, a broader range of ages is more likely to represent a healthy stock. The number of above average yearclasses in the summer RV survey, ages 4-10, is a measure of age structure. This indicator has been increasing since 1996 and all ages were above average in 2002 (Figure 21). This decreased by one age in 2003. This may not be the best indicator of age structure because it is insensitive to the relative contribution of older ages within the age distribution, which are thought to have a higher reproductive potential. Further research in the development of this index is required.

Several indices can provide insight into the distributional properties of abundance. The stratified proportion of the area associated with non-zero RV survey sets is a measure of the area occupied by a species. Area occupied by haddock 43cm and greater in length (approximates ages 4+) has shown an increasing trend since the late 1980s and is near the high levels seen in the late 1970s and early 1980s (Figure 22). The area occupied by haddock 26-42cm in length (approximates ages 2 and 3) has shown an increasing trend since the late 1980s and was at the highest levels observed in 2001 (Figure 22). Although this indicator has decreased in the last 2 years, it is still above the long-term mean.

The average catch rate in annual survey sets where a species occurs is an indicator of the local density of the species. Local density in the RV survey of haddock 43cm and greater has shown no trend over the entire time period (Figure 22). The local density in the RV survey of haddock 26-42cm has been increasing since the early 1990s and is near the highest levels observed in the series (Figure 22).

Mean lengths-at-age of 4X/5Y haddock in the summer RV surveys decreased through the mid-to late 1980s (Table 13, Figure 23). Some recovery occurred in the late 1980s and early 1990s, but not to the sizes of the earlier period. Mean lengths-at-age have been decreasing since the early to mid- 1990s, particularly at older ages. Mean weights-at-age show similar trends (Table 14, Figure 23). Most ages are below long-term mean and many ages are at or near the smallest size observed. We do see small increases in last year or two for some ages, suggesting that the trend may be stabilizing. When the Scotian Shelf and Bay of Fundy components are examined separately, the trends are similar although the decrease/recovery in the late 1980s/early 1990s is less apparent in the Bay of Fundy (Figure 24). A comparison of weights-at-age from the commercial fishery and from the RV survey, show similar trends at ages 7 and 9, but some differences at age 5 in the recent period and different trends at age 3, suggesting that age 3 is not fully recruited to the fishery and that age 5 has become less so in the last 5 years (Figure 25).

The instantaneous annual growth rate (G) calculated using length at ages 2-4 and 5-7 for haddock from the summer RV surveys shows a long-term decreasing trend since the mid-1970s, but shows some signs of stabilising in the last few years (Figure 26). The trends in growth rates between the two age groups are similar.

An index of fish condition, Fulton's K, developed for haddock from the summer RV surveys, has shown a decreasing trend since the early 1980s and reached a minimum in 2002 (Figure 26). Low levels of this index in Atlantic cod have been related to poor reproductive success, and to post-spawning mortality at very low levels (Dutil and Lambert 2000). Similar experiments have not been conducted for haddock but should be. It would appear that the levels observed here for 4X/5Y haddock have not affected reproductive success or survivorship. However, poor condition does reflect low productivity.

Total mortality (Z) estimated for ages 5-7 (historically fully recruited) from the summer RV surveys was relatively stable in recent years with an implied fishing mortality of about $F_{0.1}$ (Figure 27). Unlike a number of other stocks on the Scotian Shelf, this estimate of total mortality does not suggest that the natural mortality for 4X/5Y haddock has increased in recent years. Relative fishing mortality (estimated for ages 5-7) showed an increasing trend through the 1970s to a maximum in the early 1980s, followed by a decreasing trend (Figure 27). Relative F increased in 1992-94, but decreased in 1995 and has remained relatively stable since then.

Industry Survey

The mobile gear <65 ft (ITQ) fleet has conducted a joint resource survey of the 4X/5Y area with DFO since the summer of 1995. The survey is conducted in July, the same time that the DFO research vessel survey is conducted, by 3 draggers (<65 ft) equipped with standardized gear with the same size codend liner as used in the RV survey. A fixed station design, based on the RV survey strata, is used and standardized tows are made. The survey is designed to cover the entire 4X area, included the large inshore area off southwest Nova Scotia not covered by the RV survey. Further details are summarised in O'Boyle et al. 1995 and Hurley et al. 1999. Due to changes in the survey design between 1995, the first year of the survey, and subsequent years, the 1995 survey was not used in the time series here.

Haddock catches in the 2002 and 2003 ITQ surveys are shown in Figure 28. As with the RV survey, haddock catches are widespread throughout most of 4X5Y, with the exception of the inshore areas off southwest Nova Scotia and in eastern 4X. Mean number and weight per tow trends and mean number-at-age per tow are shown in Figure 29. Both mean number and mean weight per tow were stable 1996-1998, then increased 1999-2001 and decreased in 2002. Mean number per tow decreased again in 2003. Haddock age composition from the ITQ survey is shown in Figure 30. The 1993 and 1994 yearclasses were also above average in this survey. The 1998, 1999 and 2000 yearclasses were all strong, but the 2001 and 2002 yearclasses were considerably lower.

Mean weight per tow of ages 4+ from this survey was also used as an indicator of abundance and has shown an increasing trend since 1996 (Figure 31). The 1998 and 1999 yearclasses made up approximately three-quarters of the 4+ weight per tow in 2003. The catch per tow of ages 2 and 3 in the ITQ survey, adjusted by the calibration coefficients for this survey from the SPA, indicates that the 1998 yearclass is the largest and that the 1999 is the second largest (Figure 31).

Estimation of Stock Parameters and Results

A traditional age-based Sequential Population Analysis (SPA) using the ADAPT framework (Gavaris 1988) was used to produce estimates of population abundance in numbers. The SPA model used is as follows:

Parameters:

Population numbers at mid-year $N_{i,2003}$ i = 2-10 Calibration coefficients $q_{1,i}$ i = ages 2-10 for July RV survey $q_{2,i}$ i = ages 2-10 for ITQ survey

Structure Imposed:

Error in catch assumed negligible
Partial recruitment fixed for age 1 in 2003
F on oldest age (10) set as average F of ages 8-9 adjusted by the partial recruitment of age 10 in 2003
No intercepts were fitted
M = 0.2 for all ages

Input:

$$C_{i,t}$$
 i = 1-10; t = 1970 to 2003 - catch-at-age for entire year (half year for 2003) $J_{i,t}$ i = 2-10; t = 1970 to 2003 - July RV survey index ITQ_{i,t} i = 2-10; t = 1996 to 2003 - ITQ survey index

Objective function:

$$\label{eq:minimise} \text{Minimise } \{ \sum \sum \left(\ln J_{i,t} - \ln q_{1,i} \ N_{i,t} \right)^2 \} + \{ \sum \sum \left(\ln ITQ_{i,t} - \ln q_{2,i} \ N_{i,t} \right)^2 \}$$

Summary:

Number of observations: 306 for July RV (9 ages by 34 years)

72 for ITQ (9 ages by 8 years)

Number of parameters: 27, 9 ln Ns estimated by NLLS, 18 qs algebraically

| age | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-------------|-------|------|------|------|------|------|------|------|------|------|
| partial | | | | | | | | | | |
| recruitment | .0001 | .033 | .118 | .452 | .884 | .972 | 1.00 | 1.00 | 1.00 | 1.00 |

The SPA inputs, commercial catch numbers-at-age, RV survey stratified mean numbers-at-age per tow, and ITQ survey mean numbers-at-age per tow, are shown in Tables 8 and 12 and Figure 29 respectively. Residuals from the model fit and summary statistics of overall fit of the model are shown in Table 15 and Figure 32. The resulting estimates of population numbers and biomass, and fishing mortality are shown in Tables 16-18. As with previous assessments of this resource, the residuals show some strong year effects, with positive residuals at all ages in some years and negative residuals at all ages in other years.

Recruitment in this stock was high through the 1970s and into the early 1980s (Table 16, Figure 33). This was followed by a ten year period of below average recruitment, from 1983-92, although the 1987 and 1988 yearclasses were near-average in strength. Both the 1993 and 1994 yearclasses were above average. The 1997 yearclass was average, the 1998 yearclass is estimated to be the strongest in the time series, and the 1999 yearclass is estimated to be the second strongest. The model suggests that the 2000 yearclass is also strong.

Spawning stock biomass (ages 4+) decreased from a peak of 69,000t in 1979 and reached a low of 19,000t in 1990 (Table 18, Figure 33). The above average 1993 and 1994 yearclasses resulted in spawning stock biomass increasing to 40,000t in 1998. The average 1997 yearclass and the large 1998 and 1999 yearclasses are estimated to increase spawning stock biomass to 67,000t in 2003.

There appears to be no relationship between spawning stock biomass and recruitment over the biomass range observed (Figure 34).

The exploitation rate on ages 5-7 (historically fully recruited) increased from the 1970s to approximately 50% in the early 1980s (Table 17, Figure 33). It declined to close to $F_{0.1}$ (20%, currently used value of $F_{0.1}$ =0.25) in the late 1980s and dropped below $F_{0.1}$ in 1994. Exploitation rate on ages 5-7 dropped again in 1999. Partial recruitment has changed in recent years due to changes in the fishery or changes in size-at-age and fully recruited ages changed from 5-7 to 8-10. The exploitation rate on older ages has remained high at about 20%.

Estimates of total mortality calculated from the RV surveys were comparable with fishing mortality estimates from the SPA (Figure 35). This implies that there has not been an increase in natural

mortality in this resource, as has been the case with a number other groundfish stocks on the Scotian Shelf recently.

Past assessments of this resource have exhibited a strong retrospective pattern, where exploitation is under-estimated and population abundance is over-estimated in the current year, relative to when additional data are available in subsequent years. The pattern of exploitation estimates in this case is variable and does not show a consistent over- or under-estimation (Figure 36). The biomass estimates do exhibit a consistent pattern of over-estimation of population abundance in the most recent year, particularly when strong yearclasses occur. Retrospective estimates of yearclass size indicate that early estimates of large yearclasses may be over-estimated by a factor of at least 2 and that this pattern of over-estimation can persist at older ages (Figure 37). This analysis estimates the 1998 and 1999 yearclasses to be very strong, which may produce this retrospective pattern again.

In 1984/1985, there was a change in the methodology used to determine ages in this resource. Concerns have been expressed that the decreases in size-at-age observed in that period may be due to changes in the methodology, not to changes in growth rate. This was investigated and it does not appear the change in methodology was the cause of these decreases. The construction of the catchat-age during this period will be investigated to determine if these decreases are a result of how the catch-at-age was produced. This would not effect just estimates of size-at-age, but also estimates of spawning stock biomass and exploitation rates during that period.

Projected yield and spawning stock biomass were calculated using recent mean weights-at-age. Weights-at-age in this resource have been declining since the mid- 1990s. If this trend continues, then yield and spawning stock biomass will be over-estimated. A shift in the proportion of landings from the Bay of Fundy to the Scotian Shelf, where growth is considerably slower, would also result in yield being over-estimated.

Outlook

Indicators of abundance (RV survey wt/tow ages 4+, ITQ survey wt/tow ages 4+, SPA biomass ages 4+, RV Survey age structure) all show increasing trends in the most recent period and all indicate that the 2003 value is near the high levels observed in the late 1970s. The large increase in 2003 4+ biomass is a result of the 1998 and 1999 yearclasses.

Indicators of recruitment (RV survey recruitment index ages 2+3, ITQ survey recruitment index ages 2+3, SPA recruitment age 1) all show that the 1998 yearclass is the strongest observed in the survey/SPA time series. The 1999 yearclass is also very strong and the 2000 yearclass is above average. Early indications of the 2001 yearclass suggest it is below average.

The distribution indicators (RV survey area occupied 43+cm, RV survey local density 43+cm, RV survey area occupied 26-42cm, RV survey local density 26-42cm) show that fish at lengths that approximate the spawning stock are near the widest area occupied observed although local density has shown no trend. The area occupied by fish at lengths that approximate recruits has decreased to but is still above the long-term average and the local density is high.

The indicators of production (RV survey growth rate, RV survey fish condition) have been decreasing since the late 1970s to early 1980s and are at or near the lowest levels observed but may be showing signs of stabilising.

The indicators of mortality (RV survey total mortality ages 5-7, SPA exploitation ages 5-7, relative fishing mortality ages 5-7) show that mortality has been low in recent years.

Projected yield was calculated using the recent partial recruitment pattern and recent weights-at-age from the fishery. Weights-at-age in the fishery are currently larger than those indicated for the population by the RV survey. Spawning stock biomass was calculated using recent weights-at-age from the RV survey. The projected yield at F=0.25 (currently used for $F_{0.1}$) for the 2004 fishing year is 11,000t and the projected spawning stock biomass (ages 4+) at the beginning of the 2004 fishing year is 67,000t.

This analysis indicates that landings of 10,000t (TAC) in the 2003 fishing year will result in an exploitation rate close to $F_{0.1}$. If fished at $F_{0.1}$, spawning stock biomass is estimated to increase to a high in 2004 and then decrease subsequently, unless further strong recruitment occurs.

Given the retrospective pattern observed in this resource in the past when strong yearclasses were present, this assessment likely over-estimates biomass and projected yield.

It is possible to estimate the uncertainties from the model regarding stock size and then use these in a risk analysis (Figure 38). The risk plot incorporates the discrepancy between the accepted model and the data. Other uncertainties not considered in this risk analysis include errors in the model assumptions, changes in fishing practices, and environmental effects on survivorship. The spawning stock biomass is currently near the high levels observed in the late 1970s; therefore a change in spawning stock biomass is not an immediate concern. Accordingly the risk analysis is done only to measure if we are keeping fishing mortality at a moderate level. The steepness of the curve indicates that the risk analysis results are relatively robust to estimation error for abundance.

Although we have observed high recruitment and recruits that are widely distributed at high local density, the spawners exhibit low growth rate, below average size-at-age, and lower condition. It is uncertain how this will impact future production.

In summary, high exploitation in the early 1980s, despite good recruitment, led to declines in spawning stock biomass. Although exploitation decreased to near $F_{0.1}$ in the late 1980s, declining production and poor recruitment resulted in further declines in spawning stock biomass. Improved recruitment and low exploitation in the early 1990s started stock rebuilding. Continued low exploitation since 1994 and the above average 1993 and 1994 yearclasses allowed spawning stock biomass to continue to rebuild. The very strong 1998 and 1999 yearclasses continued this trend.

Spawning stock biomass is currently near the high levels observed in the late 1970s, due to record high levels of recruitment and low recent exploitation levels but will decrease unless further strong recruitment occurs. Emphasis should be on how the potential yield from the current good recruitment is to be utilised over time, and on the implications of that decision for 4X cod conservation, as a result of the mixed fishery issue. Based on this, caution should be exercised in setting the quota for 2004 and the potential yield of 11,000t should be considered a maximum.
